THE CONVALESCENT.

During the period of convalescence, 'Petrolagar' brand paraffin emulsion may be prescribed with gratifying results. It mixes thoroughly with the intestinal contents and restores normal peristalsis without irritation.

'Petrolagar' avoids any apprehension or anxiety as to the functioning of the bowel during the days when the patient is slowly regaining strength.

Disorders of the Alimentary Tract

In those functional disturbances of the alimentary tract, caused by dietetic indiscretions (or excess) or by the toxaemias of more serious pathological conditions, Andrews Liver Salt will be found most helpful.

INDICATIONS—Gastric catarrh (from whatever cause), flatulence, catarrhal jaundice, constipation, especially in haemorrhoids, gout, rheumatism, pregnancy, and migraine.

ACTION—It is antacid, and a gastric sedative. Stimulates the secretion of bile and of mucus glands. It increases the fluid content of the bowel, and produces gentle painless peristaltic contractions.

CHARACTERS — A pleasant-tasting effervescent saline aperient. It gives off CO_2 with brisk effervescence in water, the solution being perfectly clear.

An 8-oz. tin will be sent free on request.

Andrews Liver Salt

ENGRAVED BRONZE WEIGHT OF THE BYZANTINE PIONEERS OF NEW TRADE ROUTES.—Byzantine Constantinople traded vigorously with many lands. China supplied silk; India, spices, aromatics, sandalwood, ivory and precious stones. The nature of these commodities reveals the luxurious life led by the Byzantines. The importance of commerce led to much pioneer exploration of trade routes. The Byzantines opened up routes to ports on the Black Sea, to trade with South Russia, and received by way of the Caucasus the silk from China for which the Persians had hitherto made them pay dearly. From ports in the Red Sea they developed trade routes east and west, and became the intermediaries to the west for many of the products of the Levant. Constantinople itself was a world-market of immeasurable importance. The existence of great and powerful bankers shows the prosperity of the city, which reached its apogee in the sixth century. The Byzantine weight here reproduced was used for weighing coins, and was found at Antioch. It is of bronze and weighs 25·120 grains. Its principal face is engraved with the heads of two personages, each with a crown and nimbus; between them are a large cross and the symbol ⟦ɔ, being the abbreviation for the ounce of six *solidi* (72 *solidi* made 1 pound).

AS A CORRECTIVE IN CONSTIPATION

PHYTATE CONTENT

To quote an eminent authority on this subject:

> "Washed wheat bran fed to cows was found to be constipating, indicating that the laxative property of ordinary bran and whole grain products is dependent not simply upon mechanical irritation, but largely, if not mainly, upon the phytates."

The special laxative properties of rye grain are well known. Ryvita is made of pure, crushed, whole-grain rye, and is rich in Phytates.

The ready digestibility of Ryvita ensures its user against starch fermentation, thus keeping the whole alimentary tract in wholesome condition.

The roughage and mineral salts of the bran ensure daily natural evacuation of the bowels.

It is usual to suggest that the patient begin by eating two or three slices of Ryvita with one meal each day.

We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

An Address on STERILITY IN WOMAN.*

BY

W. BLAIR BELL, B.S., M.D.Lond., F.R.C.S.Eng., F.A.C.S.,

PRESIDENT, BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS; PROFESSOR OF OBSTETRICS AND GYNAECOLOGY IN THE UNIVERSITY, AND OBSTETRICAL AND GYNAECOLOGICAL SURGEON, ROYAL INFIRMARY, LIVERPOOL.

In any study of sterility in the human race we should try to discover what is the trend: is sterility more common to-day than it was, say, fifty years ago? This must be a matter of sociological and national importance in some of its aspects as they are related to conditions of environment. Moreover, we must consider the effect of sterility on the health, character, and outlook of the individual woman, both in respect of her own personality and in relation to the circle in which she lives. We know, indeed, the influence of a happy family life on those immediately concerned, and we fully realize the importance of it to the nation at large. So it is that, properly considered, the question of sterility becomes a large and weighty issue.

In a remarkably short space of time, certainly not more than forty years in this country—indeed, it is only 130 years since Malthus's book on the limitation of population was first published—the control of childbirth has become common enough to vitiate statistics in regard to sterility, fertility, and fecundity, especially in relation to the upper classes. It would be impossible to-day to collect figures as accurate in regard to sterility and fecundity as those set out in the following table, which illustrates the fertility of women as estimated by Matthews Duncan from data given in the registers of Glasgow and Edinburgh in 1855.

TABLE I.—*Influence of age on the fertility of married women. Showing the percentage bearing a child within two years of marriage.* (*4,500 marriages.*)

Age when married.	Percentage bearing child within two years.
16	12.9
17	30.0
18	46.4
19	57.8
20–24	90.51
25–29	75.8
30–34	62.9
35–39	40.9
40–44	15.4
45–49	4.3

Matthews Duncan points out that these figures are not absolutely correct, for dead children are not reckoned in the records from which they were obtained. Still, he regards them as indicative of fecundity at different ages at that date. As a matter of interest my house-surgeon, Mr. Jeffcoate, obtained for me the figures shown in Table II, from the histories of more than 1,000 consecutive married women attending a gynaecological out-patient clinic.

TABLE II.—*Fecundity in relation to the age of 1,000 consecutive married women attending a gynaecological out-patient clinic. Showing percentage bearing a child within two years of marriage.*

Age when married.	Percentage bearing child within two years.
16	86.7
17	85.2
18	90.9
19	90.4
20–24	83.1
25–29	71.9
30–34	62.5
35–39	52.0
40–44	29.0
45–49	0

These figures show no resemblance to those of Matthews Duncan so far as the younger women—16 to 20 years of age—are concerned. The reason seems to be that the figures collected from an out-patient gynaecological clinic are concerned with a group of women who for the most part are parous: indeed, 56 per cent. pre-ented themselves for the relief of obstetric injuries. In this class of woman contraceptive measures do not appear to be widely practised, and if we wish to discover the influence of contraceptive measures we must study the Registrar-General's figures concerning the general birth rate.

According to the latest official statistics it appears that the birth rate per 1,000 of the population has fallen from 32.3 in the eighties, and 29.4 in the nineties of last century, to 16.3 in 1929, for England and Wales generally, and to 15.9 for London. The gap between the birth rate and the death rate is, it seems, being rapidly closed. In the last forty years, which is the period of birth control, the birth rate has dropped to one-half of the previous level. Moreover, in the Registrar-General's Decennial Supplement (1921), under the section on "Occupational Fertility," it is stated that in Class I—the highest grade—the fertility rate per 1,000 married males under 55 years of age is nearly half that of Class V (unskilled workers). Since the wives are included and births alone are taken into account, the term "fecundity rate" would be better than "fertility rate." No account has been, or could be, taken as to the exact influence of contraception, but it must be clear that this factor has been concerned in the upper classes, otherwise their low fecundity rate is inexplicable. Such a state of class sterility could not occur naturally.

According to Matthews Duncan the Glasgow and Edinburgh registers indicated that 15 per cent. of all marriages were sterile.

DEFINITION OF STERILITY.

The definition of the term "sterility" has never been satisfactorily determined. Matthews Duncan wrote: "Sterility is generally considered to imply the condition of a woman who, under ordinary favourable circumstances for reproduction, does not bring forth a living and viable child. But the term is used with many other meanings. . . ."

Quite recently, in a discussion at the Royal Society of Medicine, there was a difference of opinion on the matter. Some held that the term should indicate failure to conceive, while others maintained, as apparently did Matthews Duncan, that abortion should be included. For myself, I think it is more exact to hold to the original meaning of the word, which was jejune, empty, or barren; so it is from this point of view I shall review the subject, and therefore shall not discuss abortion. It is necessary to add that sterility may be primary or secondary—that is, after previous fecundity—and that it may be absolute or permanent, or temporary and curable.

CAUSES OF STERILITY.

In the first place it may be said that it is unscientific, and often inhumane, to subject a woman whose only complaint is sterility to what may be tiresome, if not painful, investigations, and perhaps to operations, until the condition of the husband has been established. It should be definitely understood that before anything is done to a woman the husband must be examined. In a considerable percentage of cases the male partner is found to be either impotent or temporarily or permanently sterile from absence or abnormality of the spermatozoa. According to Matthews Duncan, Gross placed the number of sterile husbands at 17 per cent., while modern writers[1] have estimated the figure at 20 per cent. in unfruitful marriages.

Apart from active contraceptive measures, which some believe may lead to subsequent sterility, and which I shall not consider further, sterility in women is due to congenital or acquired lesions in the generative organs, or to some disordered physiological state, and somewhat rarely to toxicological factors.

Congenital Lesions.

These consist of (*a*) atresiae, which are often amenable to operative procedures; (*b*) malformations, which may or may not be remediable by surgical intervention; and (*c*) underdevelopment or absence of essential organs—the latter producing, of course, absolute and permanent sterility, whereas slight underdevelopment may be curable if treated soon after puberty.

*Delivered before the Nottingham Medico-Chirurgical Society on February 12th, 1930, with lantern illustrations.

The recognition of the stenoses of congenital origin that may occur in the vagina and cervix is not difficult, and the treatment is well defined. The subsequent result in regard to conception depends chiefly on whether the uterus and tubes have been permanently damaged by the back-pressure of retained menstrual secretions. So also in regard to malformations: some of these, especially conical and hypertrophied cervices, can readily be corrected by simple surgical procedures, and sterility may be relieved. Underdevelopment (hypoplasia) of the genitalia I shall consider later, for it is, strictly speaking, the result of disordered function.

Acquired Lesions.

On these some stress must be laid, for there is none, apart from those which are the result of eradicative procedures, that cannot in favourable circumstances be remedied. The lesions fall into three groups—anatomical, neoplastic, and infective derangements. They may act directly by preventing the spermatozoa from reaching the cavum, or indirectly by causing dysparenuia, and so by interfering with coitus.

1. *Anatomical Derangements.*

Retroversion of the Uterus.—Whatever other symptoms may be caused by backward displacements of the uterus, there can be no two opinions as to the frequency with which sterility is caused by retroversion. The usual explanation, and it seems a sound one, is that the spermatozoa are unable to reach the cervical canal, for the external os may so point forwards as to lie in close apposition to the anterior vaginal wall and be occluded by it. If the position of the uterus be corrected conception may follow almost immediately. Undoubtedly many women have become pregnant with the uterus in the retroverted position, and it is not unlikely that in a certain number of these there has subsequently been a retroverted gravid uterus, though in some the malposition may have been spontaneously rectified. The whole picture, however, lends support to the view that married women, in whom no other cause is found for sterility, should have the position of the uterus corrected by operation. In a number of cases of "puerperal retroversion" there is some streptococcal infection binding down the uterus, tubes, and ovaries, and frequently the tubes are occluded by adhesions only. This is one of the causes of so-called "one-child sterility." When these adhesions are separated and the uterus is fixed in the normal position with the tubes and ovaries suspended the patient is no longer sterile.

Prolapsed ovaries may be associated with retroversion of the uterus; but it is not at all uncommon to find a prolapsed and tender ovary without any other lesion, and this may cause severe dysparenuia, and, as a consequence, sterility. In a married woman such a condition always demands treatment.

Trauma, for the most part operative, may result in the disappearance of essential parts of the generative organs, or in their mutilation to so great an extent as to prevent conception. I have always been a strong advocate of conservative measures in operations on the female genitalia; and by this I mean that while all permanent lesions causing symptoms should be removed, or otherwise dealt with, the surgeon should be careful never to remove unnecessarily or to interfere with the function of healthy structures. That, of course, should be the guiding principle in all operative procedures, but in no other part of the body is it more important that there should be strict adherence thereto than in the genital organs of a woman, whose whole life may be clouded, and perhaps her mentality affected, by too drastic procedures.

Further, the danger of rendering a young woman sterile by an imperfect operation must be mentioned. In the performance of posterior colporrhaphy, for example, a "sump" should always be left in the natural position of the posterior fornix in which the semen can collect. A circular amputation of the cervix obliterating the fornices may cause sterility.

It is necessary to call attention also to the possible danger of *curettage* for sterility. There is no need for this procedure, even though dilatation of the cervix be performed. On at least three occasions I have found occluded tubes after curettage had been performed, and it appeared probable that the occlusion had followed a slight streptococcal infection of the uterus after curettage; but, of course, one cannot be absolutely sure of this. Nevertheless, if there was pre-existing tubal occlusion, why was curettage performed?

Under this heading I must mention the danger of producing sterility in young women when *x* rays or radium are applied for menorrhagia. Valuable as radium is in certain cases, the greatest care is required in its use; so it is better to give small, and if necessary repeated, doses rather than large doses. There are, however, comparatively few cases in which this type of treatment is really indicated in young women.

2. *Neoplasms.*

Neoplasms of the body and cervix of the uterus may or may not cause sterility; much depends on the position of, and the secretions from, the tumour. The treatment of malignant tumours cannot be viewed from the standpoint of sterility, even in young women, but innocent new growths require careful consideration, fibromyomata especially. Usually fibromyomata require treatment, and their presence becomes known because of associated symptoms, such as haemorrhage, requiring relief. Nevertheless, in women under or in "the thirties" the surgical treatment applied must, when possible, take into consideration the practicability of preserving a functional organ. Innumerable cases are on record of subsequent conception in these circumstances. This statement applies equally to the removal of ovarian innocent tumours. I can recall patients from whom I have enucleated fairly large bilateral cysts or have excised endometriomata from the ovaries who have subsequently borne children.

3. *Infections.*

It is always dangerous to give figures which are based on numbers too small and are applied to conditions in regard to which associated factors are of a very variable nature. Still, it appears probable that about 40 per cent. of all cases of sterility in women are due to this cause. Fortunately we have enough clinical experience and pathological knowledge on which to establish our methods of relief in a certain percentage of these patients.

We know that the local lesions caused by the gonococcus are far more enduring and serious, so far as sterility is concerned, than those due to the streptococcus; and these are the two commonest organisms responsible for failure to conceive. The vagina of the adult, covered as it is with squamous epithelium, is rarely seriously enough infected to give rise to contraceptive discharges. The cervix, on the other hand, may be deeply infected by the gonococcus, which finds a harbour in the racemose glands, and, even though it may soon perish, such damage as it has caused is difficult to cure. There may be a copious semi-purulent discharge, and this may alter the normal acidity of the vaginal secretions—which should contain not more than 0.5 per cent. of lactic acid—and render it inhospitable to the spermatozoa. This perhaps is infrequent; still, the cervix may be a focus of infection which should always receive attention before conservative operations are performed on tubes occluded by inflammation, to which I shall now refer, just mentioning in passing that the endometrium usually escapes serious lesions, owing, probably, to the monthly regeneration that takes place.

Tubal Occlusion.

Occlusion of the Fallopian tubes is a causal lesion—long recognized in the more serious forms—of sterility. The condition has come into prominence in the last few years owing to the recognition of the minor lesions of infection with obstruction by means of the so-called "patency test" of Rubin. It is well known that the tubes may be occluded, and the patient thereby rendered absolutely sterile, without physical signs or symptoms, or even a history indicative of the state of the tubes. This has been so in 35 per cent. of the cases of sterility without

apparent cause under my care in the Liverpool Royal Infirmary which have been submitted to the patency test during the last few years. There have been eighty-two *in all of such cases.* Hunner and Wharton[10] state that in 30 to 45 per cent. of all cases of sterility the tubes are occluded. In these cases there has usually been appendicitis with pelvic invasion, or a mild gonorrhoeal infection; more rarely there has been puerperal or other streptococcal involvement. In all cases, therefore, in which the husband is found to be normal it is advisable to test the patency of the tubes before any other step is taken, unless some well-defined pathological condition is present which of itself necessitates laparotomy.

The method employed is comparatively simple, and there is really no necessity to use the expensive and rather complicated pieces of apparatus introduced at first. I became acquainted with this procedure when I was in America in 1921; but I have myself always pumped air slowly into the uterus with a rubber double-ball syringe and tube connected with a sphygmomanometer through the metal uterine catheter employed by Rubin. The air is filtered through wool plugs placed in the glass T-shaped manometric junction tube. It is important, of course, that there should be no leakage; consequently I test the apparatus prior to use on an artificial rubber uterus.

Experience enables one accurately to gauge the amount of air injected. Originally CO_2 was used instead of air, and no doubt this gas is more rapidly absorbed from the peritoneal cavity than is air. If an unnecessarily large quantity of air is pumped into the uterus and on through the tubes, for twenty-four hours there may be a certain amount of discomfort with pain in the neighbourhood of the right scapula, due to the downward displacement of the liver by the air which collects under the diaphragm and gives the diagnostic feature of patency of the tubes on *x*-ray examination of the abdomen. Radiographic observation, however, is often an unnecessary refinement, for anyone experienced in the method is usually able to tell by the way the manometric needle falls after reaching about 80 mm. Hg of pressure that the air is passing into the peritoneal cavity. Moreover, it can be heard whistling through the abdominal ostia of the tubes if a stethoscope is placed on either side of the hypogastrium. The uterine catheter, which is fitted with a rubber or metal obturator, is held firmly in the cervix gripped on either side by volsella forceps, otherwise the air will escape. If there is any doubt the cervix can be submerged in saline solution and any escape of air noted. I have never found this necessary. The free perforated end of the catheter should not extend more than 1½ inches into the cavity of the uterus. If the first test is not positive, a second test should be made shortly afterwards, for occasionally there is spasm of the isthmial portion of the tube which produces temporary occlusion.

In cases of doubt, and in those in which it is important to define the site of obstruction, it is advisable to test also with lipiodol, 6 to 8 c.cm. of which are injected with a syringe attached to the uterine catheter into the uterus. A subsequent *x*-ray examination gives a clear picture of the result. It may here be added that one of these methods of testing the patency of the tubes should always be practised about three weeks subsequently to conservative operations; such as salpingostomy, performed to relieve occluded tubes. We have in them a method of testing the perfection or otherwise of our operative procedures.

There is one other interesting point in regard to patency testing with air or CO_2, and it is this: somewhat rarely a woman previously sterile conceives after tubal inflation alone. Apparently in such circumstances there has been slight "glueing" or adhesion of the tubes, and this is broken down by air pressure. It is important to test the tubes, however, with a pressure not greater than 200 mm. Hg lest rupture from over-inflation be brought about. A few instances of collapse of the patient after inflation have been reported. I have not seen this accident.

When the abdominal ostia are patent the region of obstruction may be identified by an air inflation method I published in 1917.[2] After the peritoneal cavity has been opened the abdominal ostia are brought into view and the nozzle of a syringe filled with air is passed into each in turn. A small quantity of air is very slowly expelled from the syringe into the lumina of the tubes, and it is noted whether it passes on into the uterus or is held up at the isthmus or in the interstitial portion. If air passes into the uterus, it can be heard "popping" through the cervix, or if the uterus be nipped between the finger and thumb the air can be felt gurgling out of the cavity. In exceptional cases coloured fluid may be injected and identified by the coloration of a vaginal swab.

Having used and described this method of transtubal inflation some years before Rubin introduced his method of transcervical insufflation, it seems that I must have had a mental air-pocket, otherwise it is difficult to understand why I did not also try transuterine inflation.

Operations for Tubal Occlusion.

Of the operations designed to restore functional integrity in regard to conception little need be said. The only procedures generally practised are freeing the tube when buried in adhesions, and salpingostomy. As already stated, the result of the operation should always be tested by insufflation subsequently. In my own cases of salpingostomy, not many it is true, I have been able to demonstrate by this means that patency has been restored in 62 per cent.; but this is by no means a guarantee that pregnancy will follow. The percentage of cases in which this desirable eventuality supervenes is small. Still conception, previously impossible, does sometimes follow, and the knowledge of the possibility has a beneficial effect on the mind of a woman who has given up hope.

It seems that tubes infected by the gonococcus, which damages the mucosa much more seriously than other organisms, except that of tuberculosis, may be made patent, yet are still inhospitable to the ovum on its descent to the uterus, or to the spermatozoa in their ascent to meet the ovum. Consequently, it is after operations performed for occlusion due to the streptococcus and *B. coli* that one expects to see, and in fact, I think, does most often see, subsequent conception.

The recent interest in occluded tubes has brought to light what may be described as congenital imperforation of the tubes, usually in the isthmus. Here one may find a tortuous cord that has no lumen. In such cases, and also when the tube is occluded in this region or at the cornu of the uterus as the result of infection, it is necessary to excise the affected portion and to implant the healthy ampulla in the uterus. I have also performed this operation successfully in the case of a tube attached to a uterine horn that was imperforate.

Sometimes, however, it is impossible to save either tube. It has therefore been suggested by Estes[8] and Tuffier[12] that in some of these cases the ovary attached to its normal vascular supply, or a graft of the ovary, should be implanted in the uterus in such a manner as to allow the surface of the ovary to project into the cavity. I have performed such operations about ten times without immediate or remote harm to the patient, indeed with considerable improvement in her general condition. Tuffier,[12] on the other hand, has reported some accidents after these procedures. In some of my few cases it is too soon to give up hope, but, so far, in none has pregnancy ensued. This, I think, is about the limit to which we can hope to go in surgical conservation of the function of conception.

Physiological Derangements.

I have repeatedly emphasized the fact that the individual metabolism of a woman is her reproductive metabolism, and that the whole group of ductless glands is concerned in its regulation, and may therefore be regarded as forming a genital system. So it comes about that during the period of individual growth before puberty the strain of menstruation and pregnancy is withheld. From this we can draw the very general and obvious conclusions: (1) Those chemical substances which are required by the growing girl are the same as those required by the foetus. (2) Menstruation is a process whereby the substances utilized by the foetus and in excess of the requirements

of the non-pregnant woman are excreted periodically. Menstruation is a constitutional disturbance as well as a local one, and doubtless some of the excretion occurs through the ordinary channels.

It is well known that a woman can conceive without having recently menstruated, and that menstruation may occur without the dehiscence of a ripe follicle, and, indeed, that the uterine periodic activity can be maintained by the ovarian interstitial cells alone.[3] It is, however, quite obvious that conception cannot take place unless there be follicular ripening and rupture. The absence of ripe follicles in an ovary may be regarded as a state of hypoplasia which may require careful investigation, for it is due to failure of function in some part of the genital system.

In many of the lower animals—for example, the rabbit—rupture of the ripe follicle occurs only on the mechanical stimulation of coitus, and possibly during what is known as "doe-jumping," when pseudo-pregnancy may follow.[3] It may be noted that for sterility in cattle veterinary surgeons sometimes practise manual rupture of cystic corpora lutea. In women we have long recognized persistence of the follicle with cystic formation not only as a cause of sterility but also of menorrhagia, and this condition is extraordinarily difficult to treat from the point of view of sterility. It seems that sometimes the failure to rupture is due to a dense tunica albuginea, which prevents the ripening follicle from rotating to the surface, but there can be little doubt, I think, in view of the correlation of function between the follicular and corpora-lutea secretions, that there is often failure of some normal physiological process in these circumstances, for we know that before puberty follicles may ripen and undergo atresia or cystic formation. Further, we know that the pituitary and the thyroid are as closely related to genital functional integrity as are the ovaries themselves, and that in many cases of congenital or acquired genital hypoplasia the functional activity of the pituitary or thyroid is at fault. Thyroid and anterior lobe (pituitary) extracts may be administered in these circumstances, but it is always extremely difficult to know, if pregnancy supervenes, whether the result can be attributed to the treatment, since so many complex factors are concerned.

I shall not discuss those abnormal conditions in the endocrine system, such as cortical hyperplasia of the suprarenal, which produce masculinity in women, with amenorrhœa and sterility. This and other related questions concerning the "genital system of ductless glands" are dealt with in my book *The Sex Complex*, to which reference may be made for a further consideration of them. It is sufficient here to record that insufficiency of the secretions of the pituitary and thyroid leads to amenorrhœa and sterility. It will be noted that all constitutional disturbances which produce sterility also produce amenorrhœa, or scanty and infrequent menstruation, partly because enough of the chemical materials required by the fœtus are not available, and this deficiency affects menstruation as well as conception.

Furthermore, experimental investigations have taught us that one of the chief chemical substances required is calcium,[4] [5] [6] and that just as a hen deprived of calcareous material in its diet ceases to lay eggs, so in similar circumstances may a woman be sterile. This is not difficult to understand when we take into consideration the strain there may be on the calcium metabolism of the mother during pregnancy and also in lactation, when, as we can readily appreciate, menstruation is normally absent. Needless to say, there are many subsidiary articles of diet and vitamins—such as D, which is believed to control the calcium-phosphorus balance—that are necessary. I purposely omit consideration of vitamin E, for though insufficiency of this substance causes infertility in male animals, sterility is not so produced in females, but early abortion follows.[7] [8] But while some chemical substances seem essential, there can be no doubt that perfect health and a full mixed diet alone should be the standard at which every woman who wishes to conceive should aim. Most harm may follow "fads" in the matter of diet. The mixed food of the ordinary citizen contains all [illegible] necessary.

Occupational and Toxicological Factors.

There seem to be no actual figures that serve to show whether occupation *per se*—apart from age of marriage, environment, and so on—has a definite influence on fertility and fecundity. Still, we do know that in those industries in which chronic lead poisoning used to be common sterility was produced in men and, to a less extent, in women. So, also, chronic alcoholism may produce sterility, and therefore occupations in which women find an opportunity for drinking may show a reduced fecundity rate.

Psychical Factors.

Civilized woman, with her "educated" outlook on sex questions, can hardly be considered an ideal female mammal from the breeding point of view. This is not directly her own fault; circumstances of over-population and environmental disharmonies have led to the suppression of natural sexual manifestations, and have fostered abnormal variations in the exploitation of sexual desire. Such widespread deviations from the strict physiological path as now exist must in time have some effect on actual fertility and fecundity. It need hardly be said that the more natural men and women are in their manner of living and loving the greater will be their power of reproducing their species. In primitive man, no doubt, as with the rest of the mammals in the wild state, and with the birds, the coquetry of courtship was the immediate prelude to mating and almost inevitable conception. It is certain that love-making stimulates the sexual functions, so the ability of some men to arouse desire in, and to fertilize, a woman who is sterile with another partner may be the whole story of what we call "incompatibility," or "selective sterility." No one can accurately foretell what will happen in the future; it is, indeed, difficult to say how much right or wrong there is in the growing assumption by Man of the prerogatives of Nature, and perhaps, after all, I should not tread on such slippery ground.

SUMMARY.

1. No woman should be subjected to unpleasant examinations or treatment for sterility *per se*, until her husband has been proved fertile. A considerable percentage of men are temporarily or permanently sterile.

2. Statistics concerning sterility in women generally are inevitably vitiated by the widespread adoption of contraceptive measures.

3. There is no evidence that women are more infertile now than they were fifty years ago.

4. Some congenital anomalies of the genital tract are amenable to treatment.

5. Of the acquired lesions causing sterility infections of the Fallopian tubes are the most prominent. Recent methods of investigation and of surgical treatment afford the hope that in some cases relief may be effected.

6. Conservation of function, when possible, should always be attempted in operations on the female genitalia.

7. Physiological derangements of the metabolism and the regulators thereof, and dietetic factors, are becoming well understood, and this may soon lead to improvements in treatment.

8. Psychical factors doubtless are responsible for both voluntary and involuntary sterility. The influence of these factors has not yet been fully investigated by scientific methods.

9. Good health, a natural mode of life, and a normal psychological outlook, in the absence of physical defects and lesions, are the concomitants of natural reproduction.

A STUDY OF PSITTACOSIS.

BY

ROBERT HUTCHISON, M.D., F.R.C.P., PHYSICIAN TO THE LONDON HOSPITAL;

R. A. ROWLANDS, M.D., F.R.C.P., PHYSICIAN TO THE LONDON HOSPITAL;

AND

S. LEVY SIMPSON, M.D., M.R.C.P., MEDICAL FIRST ASSISTANT TO THE HOSPITAL.

WE describe below 27 cases of psittacosis that have come to our notice during the last few months. Of this number, 18 occurred in the London area, and the parrots associated with the remaining 9 cases were purchased from bird-shops in London. The majority of the cases have been seen by one or other of us, and several have been observed throughout the greater part of their illness in the wards of the London Hospital. Of the 27 patients 5 died. Three of these deaths, however, occurred in one virulent family epidemic, involving five people.

Prior to the present epidemic of 1929–30 psittacosis was almost unknown in this country except for a few sporadic cases. It has, however, been recognized as a disease, and the association with parrots noted, for fifty years. Its rarity in recent times has tended to cause it to be forgotten, and this fact, coupled with an uncertain bacteriology, resulted in a sceptical attitude in the diagnosis of the cases that occurred early in the recent epidemic. In fact, many of these were not unnaturally thought to be atypical typhoid, or influenzal pneumonia, and it was only through a letter inserted by one of us in the medical press that many of the cases came to our knowledge.

The history of psittacosis constitutes an instructive epidemiological study, and has helped in the appreciation of many features of the present epidemic.

EPIDEMIOLOGY.

In 1880 Ritter[1] described a small epidemic in Ulster, Switzerland. Seven persons were affected, of whom four lived in the house, one came daily, and the remaining two came to clean or repair bird-cages. The owner of the house was a bird collector, and parrots and other exotic birds had arrived a few weeks previously from Hamburg, and also from Vienna. Some of the birds died, and the remainder were killed as suspect. Three of the seven patients died.

Small outbreaks were observed by Ost[2] in Berne (1882), and Wagner[3] in Leipzig (1882 and 1886). The Leipzig outbreaks are of great interest, for although some of the cases were caused by sick parrots, three cases in one household were apparently due to a sick dog bought from the parrot shop. The dog died.

The first extensive outbreak occurred in Paris in 1891–92. There were 50 cases, with 16 deaths in the first year. Smaller outbreaks occurred in the next few years. The Paris epidemic was investigated by several workers: Dujardin-Beaumetz,[4] Dubief,[4] Nocard,[5] Siéard,[5] Gilbert and Fournier,[6 7 8] etc. M. Dujardin-Beaumetz[4] made the first report to the Council of Hygiene. Two Frenchmen, Dubois and Marion, brought a consignment of parrots from Buenos Aires to Havre. Of 500 birds, 300 died on the voyage. The two men fell ill, and the surviving parrots were distributed. All the subsequent cases except three could be definitely traced to contact with this batch of parrots. It is a matter of historical interest, however, that Dujardin-Beaumetz, in his first report, suggested that this was merely coincidence, and that they were dealing with an epidemic of influenza, and not a new illness imported into the country by parrots. In January, 1893, Dubief[4] described two small epidemics originating from such parrots in different quarters of Paris, and Dujardin-Beaumetz was so impressed by the evidence that he asked leave to withdraw his original opinion, and to state, "I think, on the contrary, that the return of these epidemics and their identical course permit me to affirm that there is a relation of cause and effect."

One of the house epidemics studied by Dr. Dubief is sufficiently interesting to report. It bears a close resemblance to one of the London house epidemics studied by us.

"At 31 de la rue de Vaugirard there exists a family pension kept by M. and Mme M. On January 31st Mme M. is taken ill with severe typhoid-like symptoms. On February 8th there occurred a very intense pulmonary congestion, and after having been through a very bad period she is to-day completely cured. But her husband, aged 62, falls ill on February 2nd with signs of infection; he is seized with pneumonia on the 8th, and dies on February 9th in the evening. The maid falls ill on February 2nd, and after having shown critical symptoms she recovers. The seamstress, aged 55, who worked in the apartment, is taken ill with signs of influenza on February 1st and dies with symptoms of pneumonia four days later. Finally, the porter of the house, aged 61, is taken ill on February 4th; he presents symptoms of prostration and depression, and in spite of a slight improvement on February 15th he dies on the 20th with symptoms of pneumonia. Thus, of 5 persons attacked, 3 died.

"The following particulars were ascertained. On January 26th, 1893, M. and Mme M. bought a parrot from a travelling tradesman; this bird was ill at the time of purchase, and it died on January 25th. It was thrown in the dustbin, and the porter was ordered to clean the cage. All the persons subsequently ill had been in contact with the sick parrot, and more particularly Mme M., who had fed the parrot from her mouth; the porter had cleaned the cage, which was very dirty from the severe diarrhœa which the parrot had in its last moments of life."

In 1896 Gilbert and Fournier[7] described further epidemics, and concluded that they were dealing with "a specific microbic illness, which may appear frequently among parrots, and which can be transmitted to man with great ease." Siéard[5] in 1897 described a family epidemic that occurred at Vassy, and Nicolle[9] in 1898 described a similar epidemic in Bernay. The cause of the latter epidemic was a sick parrot which was sent from Paris, and which died a few days after its arrival. In a review in 1926 Gilbert and Fournier[8] conclude that "the transmission of psittacosis to man is no longer in doubt: it occurs more easily when the animals are the receivers of particular care, especially coddling and mouth-to-beak feeding."

Following upon the Paris epidemics, outbreaks also occurred in Italy, and the Rome correspondent of the *Lancet*[10] in 1897 quotes a manifesto of the Civic Ufficio d'Igiene, in which it is stated that "two parrots, recently arrived in Genoa, by the steamship *Manilla*, set up two 'focolai' (centres of infection) of the aforesaid disease, and this has caused a number of victims." It is reported that there were 14 cases, 8 of them fatal. This was followed by further outbreaks at Florence, and later at Udine.

In 1899 Leichtenstern[11] reported further epidemics in Germany, especially in Cologne. He quotes Haedke's observation of a small outbreak in Stettin in 1896, where four members of a well-to-do household were infected from a sick Amazon parrot. There were several outbreaks in Cologne in 1898. The first occurred in a perfectly conducted hygienic household in Quirinstrasse, consisting of mother and father, six daughters, and two sons. Of these ten people only the youngest daughter, aged 14, escaped infection. Four of the nine patients died. The sick parrot was a green Amazon from Brazil. The bird died. A similar type of parrot, also recently imported, caused an outbreak among another Cologne family of the name of Laurenzi. Eight people were taken ill, but only one died. A further outbreak occurred in Bismarckstrasse, there being five cases and one death. This house epidemic was attributed to two recently imported grey parrots. The Krefeld epidemic of 1899 (11 cases in a hotel) is of interest in that the birds concerned were sick popinjays and finches.

In 1904 Vickery and Richardson[12] reported a small family epidemic of psittacosis in America. McClintock[13] (1917) records an epidemic in Wilkes-Barre, Pennsylvania, which originated in the basement of a large department store. Many of the parrots were ill when they arrived at the store and a large number died a few days later; many of the parrots were sold. A careful analysis was made of the clerks located near the parrots.

"In about ten days the sick list of the store employees began to grow. At about the same time many peculiar cases of illness appeared in the practices of physicians in Wilkes-Barre and the surrounding towns. The patients usually gave a clear history

of contact with the sick parrots, either at the store or at home. . . . Some people touched the parrots, but in the majority of instances the inspiration of the air of this zone was the common factor. . . . There were a number of human cases in which the disease in its epidemic form must have been contracted from sick parrots, after the birds had been taken to the homes."

In this country Beddoes[14] described two cases, aunt and niece, that occurred in 1914. A sailor relative brought home a sick parrot from his ship. Several of the sailors were unwell, and one was taken to hospital at Liverpool with supposed typhoid. In 1924 Gulland[15] reported two cases in this country, and in 1927 Stolkind[16] recorded a further two cases. In July, 1929, Thomson[17] investigated a small outbreak of four cases occurring in Birmingham. It is of great interest to note that psittacosis in the summer of 1929 occurred in epidemic form in the Argentine. This suggests that the mode of transit of the parrots from the Argentine to Europe is not necessarily responsible for the initiation of the disease, but rather for its spread among the birds.

Weekly Bulletin No. 48 of the Health Section of the League of Nations, dated November 28th, 1929, states that according to unofficial information received from the Argentine there was an outbreak of psittacosis in October, and cases of this disease were reported from various parts of the country. The epidemic is said to have begun at Cordova, among a theatrical company possessing a parrot which was suffering from the disease.

The Epidemiological Record of the League of Nations, December 5th, 1929, states:

"Argentine medical journals contain some details concerning the epidemic of psittacosis which broke out in that country at the end of the summer. During July and August the town of Cordova reported many cases. Psittacosis was only diagnosed a considerable time after it had made its appearance, when the source of the contagion was traced to a disease of parrots. A few days after the epidemic started at Cordova there was another outbreak at Alta Gracia, a watering place 35 kilometres from Cordova. Another epidemic was noticed in the town of Tucuman, also situated in the interior of the Argentine where the Andes rise. This town is directly connected by rail with Cordova. Lastly, cases have been recorded at Buenos Aires. Altogether several hundreds of cases—all connected with sick parrots—have been recorded in the Argentine. Accordingly this seems to be the largest epidemic of psittacosis hitherto known. A committee of inquiry has been appointed by the Tucuman Council of Health, and another inquiry is being carried out by the Argentine Medical Association."

During the last few months epidemics of psittacosis have occurred in the United States of America, in many parts of Europe, and in this country. Thomson[17] of Birmingham has studied a fresh series of cases, and we have investigated 27 cases, of which 18 occurred in London. Most of these cases have been caused by recently imported green Amazon parrots, and it would thus appear that the pandemic among parrots in South America is largely responsible for the subsequent European outbreaks.

LONDON HOSPITAL SERIES.

GROUP A. (Walworth, London.)

In this group five people were affected, of whom Mr. and Mrs. M. lived in the house, Mr. B. came to work there every day, and Mrs. O'N. and Mrs. S. visited.

The place was a public-house, and on November 8th a green Amazon parrot was bought from a hawker over the counter. The bird sickened and died on December 8th, when it was replaced by another parrot, which was bought in similar fashion, and which died on December 22nd. The parrot was petted and fed by Mr. and Mrs. M., in the latter case from mouth to beak.

Mrs. M. was taken ill on December 21st, and her husband on the following day. The next to fall ill (December 23rd) was the potman, Mr. B. His degree of contact with the birds is not definitely known, except that he handled both the birds after their death. Mrs. O'N. began to feel unwell at the beginning of January (? 4th). She handled the dead parrot on December 22nd. Mrs. S. fell ill on January 12th. Apparently she had never touched the birds or fed them, but had stood sometimes by their cage. However, it would appear that she was not taken ill until twenty-one days after the death of the second parrot, a period much longer than the usual incubation period. She had nursed Mrs. M. throughout her illness, and had, from alleged sentimental reasons, used the same handkerchief as Mrs. M. We are inclined to regard her as a case of infection from one person to another. The other four cases were apparently directly infected from the parrots. The three women were sisters.

Of the five patients the potman, Mr. B., an alcoholic individual, succumbed after a brief illness; the remaining four were all seriously ill, with danger to life, but eventually recovered.

CASE 1.

E. M., *female, aged 45.* This patient was taken ill with general malaise on December 21st, 1929. She continued thus until December 25th, when she developed a painful dry cough and a pain in the right side. On examination she was found to have an impaired percussion note and crepitations at the right base. The temperature was 102° F., with slight increase in pulse and respirations. About this time the patient suffered from photophobia and deafness. Within the next few days the pulmonary signs and symptoms increased in intensity, the temperature being maintained at about 104° F., the pulse becoming rapid, feeble, and irregular, and the respirations increasing to as much as 60 a minute. The physical signs were those of a broncho-pneumonia. The patient became very somnolent, collapsed, and cyanosed, and cardiac stimulants and oxygen were used. She remained in this precarious condition for about a week, and then began to show slight improvement. On the eighteenth day of the illness the temperature began to fall slowly (lysis), but the lung signs did not clear up for several days after this. At the height of the illness blood cultures were sterile, and the blood count showed a leucopenia. Agglutinations to typhoid, paratyphoid A and B, and *B. aertrycke* were negative. Convalescence was slow and tedious.

CASE 2.

R. M., male, aged 54, fell ill about December 22nd, 1929, but was not seen by a doctor until December 25th. He then had high fever, with persistent cough, but no signs in the lungs. The next day the temperature was 104° F., and dullness and moist sounds were present at the right base. The patient was semi-comatose and delirious, with outbreaks of restlessness and noisiness. Constipation and distension of the abdomen were marked features. The high temperature was maintained for about ten days, after which it gradually fell to normal, and the lung condition resolved. At the end of the first week of the illness the patient developed very obstinate hiccup, which persisted for some days. Convalescence was slow and tedious.

CASE 3.

J. O'N., female, aged 49, began to feel unwell on January 4th without having any very definite symptoms. She developed a slight cough after a few days, and took to bed on January 11th. She then complained of severe frontal headache, weakness, cough with slight sputum, sore throat, and photophobia. She became restless and feverish at night, and was unable to sleep. Constipation was troublesome. The patient was not seen by a doctor until January 16th, when her temperature was 101.5° F., her pulse rate 92, and respiration rate 25. Headache was now very severe, a dry cough had become worse, and there were a few crepitations at the base of the right lung. When visited on January 18th the patient lay quietly in bed with all the blinds drawn, as she could not bear the light. She complained bitterly of her headache, which was not relieved by analgesics. It was stated that she had periods of delirium. The lung signs were the same as on January 16th. The spleen was not palpable. The temperature had fallen to 100° F. that morning, but the next day the patient had a rigor and the temperature rose to 105° F. It persisted at this level, with only slight morning remissions, for another week, after which it fell by lysis. The respirations and pulse were never markedly raised. On January 21st there were numerous moist sounds at the base of both lungs and extending up to the scapula. There was slight dyspnœa and some cyanosis. The patient occasionally lapsed into a muttering delirium. On January 31st the temperature was normal, although the patient still seemed slightly incoherent, and as though she did not fully realize what she was doing. On February 2nd there was a relapse, the temperature rising to 102° F., following upon a rigor. This apparently was associated with a thrombosis of the right femoral vein. The next day the temperature was subnormal. The patient then gradually improved, and on February 11th was convalescent, although the leg was still swollen. Agglutination tests for typhoid, paratyphoid A and B, and *B. aertrycke* were negative during the second week.

CASE 4.

M. S., female, aged 56, was taken ill on January 12th with general malaise and weakness. On the second day a severe headache and backache developed. Her temperature was 104° F., her respiration rate 24, and her pulse rate 98. On January 14th the

patient was very confused and complained of vague abdominal pain, chiefly in the iliac regions. Apart from some distension of the abdomen there were no definite physical signs at this time. The next day the confusion and collapse increased, and there were periods of delirium. On one occasion she jumped out of bed and rang a bell, afterwards stating that she had no reason for doing so. The patient was very restless at night, and could not sleep. The headaches persisted in spite of numerous analgesics. A troublesome dry cough developed. Constipation and anorexia were well marked. Photophobia was present. On January 19th (seventh day of illness) she was admitted very ill to the London Hospital. She lay in a semi-comatose condition, without taking any interest in her surroundings, even when aroused. Her cheeks were flushed and her tongue dry and furred. There were some moist sounds at the base of the right lung. The abdomen was distended, and the spleen was not palpable. Her temperature was 103° F., her pulse rate 92, and respiration rate 24. She remained in this state for about a week, the delirium and troublesome dry cough being prominent features. The moist sounds at the base of the right lung increased, and on January 27th the percussion note was impaired and an area of tubular breathing was present at the angle of the right scapula. At this time (fifteenth day of illness) the temperature was falling by lysis, and on January 28th it became subnormal, persisting at this level until the patient's discharge, two weeks later. During the first week of the afebrile state the patient's general condition was precarious, but subsequently there was gradual recovery. Moist sounds were present in the lung for about ten days after the temperature had fallen. Agglutination tests on January 20th were negative for typhoid, paratyphoid A and B, and *B. acertrycke*, and blood cultures were sterile. The urine contained a trace of albumin, leucocytes, and epithelial cells, and gave cultures of *B. coli* and *B. proteus*. A blood count on the eighth day showed: erythrocytes 4,700,000 per c.mm.; haemoglobin 64 per cent.; colour index 0.65; leucocytes 5,760, polymorphs 81 per cent., eosinophils 0.5 per cent., small lymphocytes 12 per cent., large lymphocytes 1 per cent., large hyaline cells 5.5 per cent.

CASE 5.

F. P. B., male, aged 53, began to feel unwell on December 23rd, but continued at his work until the 28th, when he complained of very severe headache and aching in all his limbs. He was admitted to an institution on December 30th with a temperature of 102° F., a pulse rate of 88, and a respiration rate of 24. He then had a slight cough, and a few moist sounds were noted in the lungs. Insomnia and marked constipation were other symptoms at this time. The headache persisted and the cough became more troublesome. On January 6th fine crepitations were present all over the right lung. On January 8th there appeared signs of broncho-pneumonia at the bases of both lungs. It was specially noted that, in spite of a persistently high temperature, the pulse had remained relatively slow, 80–100. The respirations, too, were only 24. A large, bright haemorrhage now occurred from the rectum. During the next few days the patient became worse, the respirations and pulse increasing. He died on January 11th. Necropsy showed lobar pneumonia of the whole of the left lung and right lower lobe, and it was thought that the patient died from influenzal pneumonia and heart failure. The case was subsequently traced as one of this group of five cases, and it would appear from the records and charts that it was much more probably a case of psittacosis with marked involvement of the lungs, as usually occurs in fatal cases of this disease.

Group B. (Barking, London.)

In this group five people were affected—two sisters, two brothers, and the mother, all belonging to one family. Apart from one of the sisters, who was married, they all lived in the same house. It is interesting to note that, whereas all these people were previously in good health, two remaining members of the family, brother and sister, suffering from phthisis and living in the same house, gave no evidence of infection with psittacosis. Two other sisters, however, also escaped infection.

J. R. bought a green Amazon parrot from a hawker in Spitalfields Market on January 10th. Although showing no gross signs of illness, it fell off its perch dead on January 21st. The patients at first considered that they had had no intimate contact with the bird, but it subsequently appeared that, except for the married sister, they had in all probability put their fingers inside the cage and stroked the parrot's head.

L. R. fell ill on January 23rd, E. R. on January 25th, J. R. on January 27th, El. R. on February 1st, and E. S. on February 6th. The first four cases appear to be direct infection from the parrot, but the last case, that of the married sister, is much more probably an example of *person-to-person* infection. She saw the parrot on only one occasion, January 12th—that is, twenty-five days before the beginning of her illness. She came to live with the R. family from February 1st, in order to nurse her mother, but she had called on the other ill patients and sat by their bed in the house for some days previous to this. The severity of the infection in this ill-fated family was very great, pulmonary complications being a marked feature. Only two survived—the married sister, E. S., and one brother, J. R.

CASE 1.

L. R., female, aged 30, was taken ill on January 23rd. She awoke in the morning feeling unwell, and at 7.45, on taking a cup of tea to her mother, she suddenly fainted on the bed. After a few minutes she recovered consciousness, and returned to her own bed feeling ill and very weak. For the next few days the patient suffered from very severe headaches, photophobia, insomnia, nausea, and a dry troublesome cough. On January 26th the patient vomited twice, and on the 28th she was admitted to the London Hospital, all the symptoms having persisted.

On admission her temperature was 102° F., her pulse rate 120, and respiration rate 36. She was cyanosed and had sordes on the lips. Numerous rhonchi were scattered throughout the lungs, and crepitant rales were present at both apices. There was no dullness on percussion. The tongue was dry and coated, and the abdomen distended. The spleen was not palpable. There were no objective changes in the central nervous system.

The headache gradually diminished in intensity, but the cough became more troublesome, sputum still being absent. There was no marked constipation or diarrhoea. On January 30th dullness and diminished breath sounds, with moist sounds, were noted at the base of the left lung. The cyanosis had increased. During the last few days the patient had become very lethargic, and she was now semi-conscious. The dyspnoea and cyanosis had increased. On February 2nd she became unconscious, and after some hours in this state died. The day before death her temperature was 102° F., pulse rate 108, and respiration rate 60.

Agglutination tests for typhoid, paratyphoid A and B, and *B. acertrycke* were all negative (January 31st), and blood cultures were sterile. The urine and faeces gave cultures of *B. coli*. A blood count on January 30th showed: erythrocytes 5,160,000 per c.mm.; haemoglobin 83 per cent.; colour index 0.82; leucocytes 10,040, polymorphs 93 per cent., small lymphocytes 4.5 per cent., large lymphocytes 1.5 per cent., large hyaline cells 1 per cent.

CASE 2.

E. R., male, aged 18, awoke on the morning of January 25th with a slight headache. He did not have any breakfast, but went to work. During the morning the headache became very much worse. It was mainly situated in the parietal region, but spread across the top of the head. He was unable to continue at work, and at 2 p.m. took to his bed, complaining of the headache, weakness, and vague pains all over the body. During the next few days the headache became worse, constipation was troublesome, and a worrying dry cough developed. On January 28th he was admitted to hospital. He was obviously very ill, but there was no mental cloudiness at this time. The temperature was 102.5° F., the pulse rate 120, and the respiration rate 36. There was no marked photophobia. Sonorous rhonchi were present at the bases of both lungs. The abdomen was not markedly distended, and the spleen was not palpable. The heart was apparently normal, and no abnormalities were found on examination of the central nervous system.

On January 29th there was considerable epistaxis, which recurred frequently during the next few days. At this time he began to expectorate some muco-purulent sputum, and increased respirations were very evident. He became very restless at night, and the next day had periods of delirium and disorientation. On January 30th he was definitely cyanosed and somewhat collapsed. Dullness and bronchial breathing were present at the inferior angle of the right scapula, with intense whispering pectoriloquy and crepitant rales. The patient gradually became semi-conscious, with periods of restlessness and excitement, during which he was restrained with difficulty from leaving his bed. On February 3rd he was very collapsed and stuporous. There was no response to questions, although he made a slight attempt to put out his tongue on being asked to do so. There were definite signs of consolidation at the base of the right lung—marked dullness and bronchial breathing. There were a few moist sounds at the left base, and numerous rhonchi scattered throughout the rest of the lungs. He was still having attacks of severe epistaxis. On February 5th his condition was even worse; he was almost unconscious, except for intermittent periods of violent excitement. The signs in the lungs were the same. The patient fell more and more deeply into coma, and died on February 9th.

On January 28th and February 5th agglutination tests were negative for typhoid, paratyphoid A and B, and *B. acertrycke*; blood cultures were sterile. A blood count on January 30th showed: erythrocytes 5,100,000 per c.mm.; haemoglobin 90 per cent.; colour index 0.89; leucocytes 7,120 per c.mm., polymorphs

71 per cent., small lymphocytes 18 per cent., large lymphocytes 3 per cent., large hyaline cells 8 per cent. Another blood count on February 5th was very similar, the leucocyte count being 6,520 per c.mm.

CASE 3.

J. R., male, aged 27, fell ill on January 27th, with throbbing frontal headache, which persisted with severe exacerbations, especially at night. He retired early to bed that day, and, although he got up the next morning, he returned to bed at midday. That evening he felt very sick and retched for several hours. On January 30th he was admitted to hospital with a temperature of 101° F., a pulse rate of 94, and respiration rate of 24. The temperature remained high for three days, and then fell within twenty-four hours to normal (February 3rd). The only complaint during the illness was the headache. There was no cough, although the lungs showed transient impaired note and diminished breath sounds at the right base, with a few scattered rhonchi. There was no marked abdominal distension, and the spleen was never palpable. There was no photophobia. Although the patient was usually quite clear mentally, he seemed slightly delirious at intervals. On February 2nd he had a profuse epistaxis. The next day he felt much better, and had a fairly rapid convalescence.

Blood cultures on January 30th were sterile. Agglutination tests on February 5th were negative for typhoid, paratyphoid A and B, and *B. aertrycke*. The faeces gave cultures of *B. coli*. A blood count on January 30th showed: erythrocytes 5,000,000 per c.mm.; haemoglobin 80 per cent.; colour index 0.8; leucocytes 7,000 per c.mm., polymorphs 70 per cent., small lymphocytes 17.5 per cent., large lymphocytes 5 per cent., large hyaline cells 7.5 per cent.

CASE 4.

El. R., female, aged 52, fell ill on February 1st, with headache and malaise. That day she had an attack of shivering, especially along the spine. This lasted for about one hour, and disappeared when she was well covered in bed. On February 2nd her temperature was 102° F., her pulse rate 100, and respiration rate 24. She developed a slight dry cough on this day, but there were no physical signs in the lungs. Photophobia was present. The bowels were constipated. On February 4th the patient was still quite clear mentally and not very ill. The cough had persisted, and there were several moist sounds at the base of the left lung. Her headache became worse during the evening, and she described it as throbbing and sore as if someone had been beating or scraping the top of the head. The headache was greatly aggravated by coughing.

During the next two days she complained of profuse sweating, and stated that the headaches made her light-headed. She found herself talking nonsense on awaking. On the morning of February 5th she vomited, and on February 6th she was admitted to the London Hospital. She was now bringing up much muco-purulent sputum and the photophobia was well marked, the blinds being drawn by request. The headache was not a prominent feature at the time. The lips were somewhat cyanosed, and sordes were present round their margins. The throat was red, and there was a yellowish exudate on the soft palate; slight conjunctivitis was present. The tongue was dry and furred, and the abdomen was distended. The spleen was not palpable. Crepitations were present at the base of both lungs, and rhonchi were scattered throughout. The heart sounds were normal, and there were no abnormal objective signs in the nervous system. On the day of admission her temperature was 104° F., pulse rate 94, and respiration rate 26.

On February 7th there were periods of slight delirium. There was a patch of bronchial breathing near the angle of the right scapula. On February 9th there was still much muco-purulent sputum, and the percussion note at the left base was dull. During the next few days respirations increased to 40 or 50; the patient became much worse, falling into a semi-stuporous condition. On February 13th 30 c.cm. of cerebro-spinal fluid were obtained under pressure, and 40 c.cm. of convalescent serum were injected intramuscularly. The patient died that day.

At the end of the first week blood cultures were sterile, and agglutination tests were negative to typhoid, paratyphoid A and B, and *B. aertrycke*. The urine and faeces gave cultures of *B. coli*. A report on a swab from the throat showed: Vincent's angina organisms, pneumococci, streptococci, and sarcinae. Blood count: erythrocytes 5,000,000 per c.mm.; haemoglobin 75 per cent.; colour index 0.73; leucocytes 3,360 per c.mm., polymorphs 75 per cent., small lymphocytes 16 per cent., large lymphocytes 5.5 per cent., large hyaline cells 3.5 per cent.

CASE 5.

E. S., female, aged 28. fell ill, on February 6th, with violent generalized headaches, sore throat, weakness, and slight cough with some muco-purulent sputum. The next day photophobia developed, and she stated that distant objects appeared double when seen in the light. The headaches continued to be very severe, and the patient became somnolent during the day and restless at night. She was admitted to hospital on February 9th, the third day of the illness; her temperature was 102° F., pulse rate 124, and respiration rate 40.

Although somewhat lethargic the patient's intellect was apparently quite clear. There was some cyanosis and respiratory distress. The cough was very persistent and troublesome, and there was some grey muco-purulent sputum. The tongue was dry and furred, and the throat was infected. The abdomen was distended, and the spleen was not palpable. The percussion note was slightly impaired over the right middle lobe, and moist sounds were heard over this area, extending anteriorly to the level of the second rib. The patient was eight months pregnant.

The next day the patient had two shivering attacks, one at 3 a.m. and the other at 8 p.m. The throat was very troublesome, but though it was congested there was no obvious exudation. On February 11th there was a further rigor in the early morning, and the photophobia necessitated an eye-shade.

Examination on February 12th showed extension of the lung infection to the base of the right lung, where there were numerous moist sounds. The headaches and sore throat persisted, but the photophobia gradually diminished. At 3 a.m. on February 16th there was a further rigor. Examination that day showed a patch of dullness and tubular breathing at the vertebral border of the right scapula. This area became more extensive the next day, and on February 18th the right base gave a dull percussion note, with tubular breathing, moist sounds, whispering pectoriloquy, and oegophony. The patient's general condition, however, was on the whole better. She stated that throughout her illness she had great difficulty in keeping awake, but on falling asleep she found that she began talking to herself and muttering. The respirations remained high, the pulse rapid, and the temperature of a swinging variety. The lung signs began to clear up on February 20th, when the temperature reached normal after an irregular fall. Convalescence was normal. Blood cultures, and agglutination tests for typhoid, paratyphoid A and B, and *B. aertrycke*, were negative at the end of the first week. The urine was sterile, but the faeces gave cultures of *B. coli*. The sputum contained pneumococci, streptococci, and *Micrococcus catarrhalis*. A swab from the throat gave cultures of *Micrococcus catarrhalis*, with a few pneumococci and streptococci.

GROUP C. (Barking, London.)

This was a small group consisting of husband and wife, Mr. and Mrs. S., who lived in a public-house. The parrot, a green Amazon, was bought over the counter, during the latter part of October, from a hawker, who had obtained it from the docks. The parrot was ill for about one month with diarrhoea, sneezing, loss of appetite, and wasting, and on December 12th, after an attack of convulsions, it fell off its perch and died. Both patients fell ill about November 21st, and both recovered after being severely ill. The association with a sick parrot did not come to the knowledge of the physician in charge until the period of convalescence.

CASE 1.

A. S., male, aged 32, fell ill on November 21st, when he felt somewhat "shivery and out of sorts." The next day he had a severe frontal headache which persisted, slight sore throat, and vomiting. On November 25th there was slight epistaxis, and the day after this the patient experienced severe cramp in the legs. The appetite throughout had been very poor. Constipation was obstinate, there having been no action of the bowels for a week.

On November 28th the temperature was 101° F., pulse rate 100, respiration rate 28. The patient looked ill and collapsed, his general appearance simulating a typhoid state. The tongue was dry and furred; the throat was injected, and there were patches of yellowish membrane on the palate. A few small rose-coloured spots were scattered over the chest. There was no dullness on percussion of the chest, but auscultation revealed crepitations at the right base and a few rhonchi at the left base. At this time there developed a slight cough with mucoid expectoration; no rusty sputum. Examination of the heart revealed nothing abnormal. The abdomen was somewhat distended, but the spleen was not palpable. A quarter volume of albumin was present in the urine. The patient's condition did not improve during the next week, the temperature swinging from 101° to 104° F., the pulse rate being relatively slow, between 82 and 112, and the respiration rate ranging from 24 to 30.

On December 3rd examination of the chest showed slight dullness, diminished breath sounds and medium crepitations at the right base, and signs of bronchitis at the left base. From December 5th to 8th the condition of the patient gradually improved, and on December 8th the temperature fell by lysis, and remained normal. At that time the abnormal signs in the chest had disappeared. The albumin in the urine gradually diminished to a faint trace. The patient made an uninterrupted recovery.

On January 1st and 8th blood cultures, and agglutination tests to typhoid, paratyphoid A and B, *B. aertrycke*, and *B. enteritidis*, were all negative.

CASE 2.

M. S., female, aged 27, felt ill about November 22nd, complaining of headache, cough, nausea, constipation, and occasional vomiting. She took her own temperature on several occasions, and once it was as high as 102° F. When seen by her private doctor on November 27th she complained of severe frontal headache, weakness, aching of body and limbs, and inability to lift her head from the pillow on account of giddiness. Her temperature was 103° F., pulse rate 110, and respiration rate 24. The patient was obviously very ill, and lay in bed in a collapsed stuporous state. The tongue was dry and furred, and the fauces red and inflamed. No abnormal physical signs were discovered in the lungs at this time; the heart and abdomen were normal; the liver and spleen were not palpable. Examination of the nervous system was negative.

The patient remained in this condition for a period of six days; the cough became very troublesome, the headache continued, and fever ranged between 101° and 103° F. On the morning of the seventh day, however, the temperature was 100.8° F.; the patient felt better and had less headache; she had slept better during the night, and the aching of the limbs was not so intense. On the evening of this day the temperature remained the same, but the patient maintained improvement. On the morning of the eighth day she complained of some pain over the right lower chest, and on examination a few crepitations were heard in the lower lobe of the right lung. The patient continued to make progress quickly during the next few days, until on the eleventh day her temperature ranged about 98.4° F. and her pulse rate was 90. *The fever abated by lysis. The physical signs in the lung persisted for about seven days after they were first discovered. The patient remained in bed for eighteen days, and convalescence was uneventful.*

In the second week of the illness blood cultures, and agglutination tests to typhoid, paratyphoid A and B, and *B. aertrycke*, were all negative.

GROUP D. (Oxford and London.)

This group consisted of five people staying in a country house in the Chilterns. Three other members of the household, although in contact with the parrot, escaped infection. A green Amazon parrot arrived at the house on December 21st, having been purchased from a London shop; the bird was never well, and died on December 30th.

Mrs. M. fell ill on January 5th, M. W. (cook) on January 7th, G. F. (a friend) and X. M. (a nephew) on the 10th, and A. B. (gardener) on about January 10th or 12th. Mrs. M., G. F., and A. B. were definitely known to have handled the parrot, the latter only after its death. M. W. had at least been near the bird on several occasions during life, but X. M. apparently merely sat in a room from which the dead parrot had been removed two hours previously. One of the patients returned to London before she fell ill, and her case is described in some detail below. We only refer briefly to the remaining four cases, as they have already been described in the *British Medical Journal* by Dr. Mary Radford.[19] All the patients recovered after being very ill.

CASE 1.

A. F., female, aged 49, returned home from the Chilterns on January 3rd, and was quite well until January 11th, when she suddenly began to feel very cold and to shiver. The shivering lasted twenty-four hours, and at the same time she experienced a very severe general headache, which persisted for a week, and then gradually got better. Her temperature was found to be 102° F., pulse rate 90, and respiration rate 26. There was no photophobia or epistaxis. A troublesome cough was present from the first, the patient feeling somewhat stifled and experiencing a sense of constriction behind the upper part of the sternum.

On January 16th there were signs of congestion at the base of the left lung. The next day there were numerous crepitations extending up to the angle of the scapula. The patient had been very constipated throughout, and the abdomen was distended. The spleen was never palpable, and there were no red spots. The patient became very restless at night, with intermittent delirium and insomnia.

On January 23rd the right lung became involved, and crepitations and patchy dullness were present at both bases. The patient's general condition, however, was beginning to show signs of improvement. Some nasal catarrh was present. On January 25th the patient further improved, though patchy dullness and crepitations were still present at both bases. The temperature was beginning to fall. Throughout the illness the respirations were not raised, and the pulse was relatively slow. On January 29th the temperature was normal, but the signs in the lungs did not disappear until February 15th. Convalescence was slow.

Agglutination tests for typhoid, paratyphoid A and B, and *B. aertrycke* were negative on January 23rd and 28th.

CASE 2.

Mrs. M., aged 50, fell ill on January 5th, and recovered after a characteristic illness of three weeks' duration. Negative agglutinations.

CASE 3.

M. W., female, aged 65, fell ill on January 7th. This patient, cook in the household, had the usual symptoms and signs, and eventually recovered. Negative agglutinations.

CASE 4.

X. M., nephew, aged 45, fell ill on January 9th or 10th, and began convalescence after sixteen days. There was a partial agglutination to typhoid (1 in 32) in this case, but this may be explained by inoculation with T.A.B. in 1916.

CASE 5.

A. B., gardener, aged 56, fell ill about January 12th, and recovered after a few weeks' characteristic illness. *A temporary relapse occurred during convalescence.* Agglutination tests (including *B. abortus*) were all negative.

GROUP E. (Hampstead, London.)

A green Amazon parrot was bought from a large London shop on October 23rd, 1929. From the first the bird had diarrhœa and its feathers were not properly "set." The parrot was taken back to the shop after the patients became ill. The two people affected had both been in contact with the parrot one cleaning out the cage. The first patient, a doctor, fell ill on November 19th and died on December 10th. The second patient, his maid, was less severely affected, falling ill on November 26th and recovering after a few weeks.

CASE 1.

D. L. T., male, aged 60, was taken ill on November 19th with sudden onset of general malaise, aching all over, and "feeling as if I had a temperature." Next day his symptoms were worse, he felt feverish and his temperature was 101° F. He complained of severe headache, and said he thought he had influenza, but was surprised that he had no catarrhal symptoms or signs.

On November 27th his temperature was 102.5° F., pulse rate 85, and respiration rate 25. His tongue was furred; he was mentally very depressed, and complained of severe headache. No abnormal physical signs were detected in the heart, lungs, abdomen, or nervous system. The urine was clear. A blood count on November 29th showed: leucocytes 6,750 per c.mm., polymorphs 72 per cent., lymphocytes 26 per cent., transitional cells 1 per cent., eosinophils 1 per cent. The agglutination reaction was negative for typhoid and paratyphoid A and B.

On November 30th he was admitted as an in-patient to the London Hospital. He was then slightly dyspnœic; there was also a little blood-stained discharge from the nose; he was drowsy, but quite rational, and still complained of severe headache. There were no abnormal physical signs detected in the lungs. Blood examination showed: erythrocytes 4,900,000 per c.mm.; haemoglobin 80 per cent., colour index, 0.81; leucocytes 10,220 per c.mm.; polynuclear neutrophils 66.5 per cent., eosinophils 2.5 per cent., small lymphocytes 17.5 per cent., large lymphocytes 7.5 per cent., large hyaline cells 6 per cent. There was slight anisocytosis.

On December 2nd he had retention of urine, but complained of no real pain referred to bladder or perineum. He was catheterized, and 32 ounces of urine were withdrawn. It was examined and reported on as follows: "Acid; albumin a cloud; no reduction with Fehling; deposit contains leucocytes and epithelial cells; cultures yield *Staphylococcus albus*." Nothing abnormal was detected in the nasal and accessory sinuses, but there was a good deal of inflammation of the nasal mucous membrane.

On December 5th he was not so well; more drowsy, greater dyspnœa, and more severe frontal headache. His temperature was 104.5° F., pulse rate 112, and respiration rate 44. The respiratory movements were rapid and shallow. Heart sounds were clear; coarse crepitations were audible for the first time over the lower lobe of the right lung; no rhonchi were heard. The percussion note was not impaired, and the breath sounds were vesicular. The abdomen was slightly distended, there was no tenderness or rigidity; the liver and spleen were not palpable. Rose-coloured spots were visible on the lower chest, and these disappeared on pressure.

Agglutination tests were negative for typhoid, paratyphoid A and B., *B. aertrycke*, *B. enteritidis*, *Micrococcus melitensis*, and *B. abortus*.

The next day his temperature was 102° F., his pulse rate 108, and respiration rate 40. In the morning he seemed fairly well; he was reading his newspaper and talked quite rationally. The sputum was definitely rusty, dyspnœa greater, and there were more definite signs in the lungs. The percussion note over the lower and middle lobes of the right lung was impaired; coarse crepitations and pleural friction sounds were audible over the same area. Three rose-coloured spots were still visible on the upper abdomen and chest.

X-ray examination of the chest gave the following information: "No obvious dullness on the screen; rather poor and diminished movement of the right diaphragm, possibly slight dullness, suggestive of a possible pleurisy, over right lower chest: No evidence of effusion."

On December 7th the sputum was blood-stained, the skin dry and hot, and he had greater dyspnoea. In the evening his condition was much worse; he took no notice of anyone around him. His temperature was 104.5° F., pulse rate 120, and respiration rate 56. Report on the urine: deep amber in colour; albumin 1/4; blood and sugar absent. The heart sounds were good. The signs of consolidation in the right lung were more marked.

On December 8th his temperature was 102° F., pulse rate 118, and respiration rate 50. The previous evening he had had a tepid sponging, after which he seemed more rational and had a fairly good night. During the morning he took more interest in people around him, and asked for his drinks, etc. He was very dyspnoeic: his skin was hot and dry, and his tongue furred and getting dry. For the first time he had urinary incontinence. The heart sounds were good and the blood pressure was 120/60 mm. The middle and lower lobes of the right lung showed typical signs of consolidation; the percussion note was dull, breath sounds were tubular, and no adventitious sounds were audible. Now also a few coarse crepitations were audible over the lower lobe of the left lung. Towards the evening he had a good deal of abdominal distension, which was relieved slightly by a small enema, rectal tube, and injection of pituitrin.

The next day his temperature was 103° F., pulse rate 110, and respiration rate 54. He had slept fairly well during the night, but still had urinary incontinence. There was now slight oedema of the feet and ankles. The physical signs in the lungs were very much the same as on the previous day. The abdomen was still distended, but no hepatic or splenic enlargement could be detected. His blood pressure was 110/65 mm. He was fairly comfortable during the evening and slept well in the early part of the night. At 4.30 a.m. the breathing altered; it became "very rapid and heavy." His pulse failed, and he died at 4.50 a.m. on December 10th.

CASE 2.

V. R., female, aged 39, was a maid employed in the house of D. L. T. She complained of general malaise about a week after the beginning of D. L. T.'s illness. She was admitted to the St. Marylebone Hospital on December 1st, 1929, having suffered from malaise, headache, and vertigo from November 26th.

Three days before admission she developed a cough without sputum, and complained of sweating. She felt weak and hot, and had a slight headache. On admission she appeared very drowsy and collapsed, her condition simulating a typhoidal state, and suggesting the preliminary diagnosis of typhoid. The tongue was moist and furred. The abdomen was slightly distended, and the liver and spleen were not palpable. Numerous coarse rales and rhonchi were heard at the base of the right lung. The cardio-vascular and nervous systems were normal. The urine showed no abnormal constituents.

On December 6th the patient had a brief epistaxis. On December 10th there were still numerous crepitations at the base of the right lung, but the general condition was beginning to improve. Throughout the illness she tended to be very constipated. The cough persisted for about ten days, but there was only slight frothy sputum, which was never rusty. Respirations throughout were usually 20, and were never above 28. The pulse was rather slow relative to the temperature. The latter was maintained at 101° to 103° F., and fell by lysis. Convalescence was slow and tedious. Agglutination tests during the second week of the illness were negative to typhoid, paratyphoid A and B, *B. aertrycke*, and *B. enteritidis*.

GROUP F. (Leatherhead, Surrey.)

This group consisted of two people, one C. L., who kept a large aviary as a hobby, and the other his gardener, S. R., who looked after the birds. In the early part of September, 1929, C. L. purchased from a London store five birds—2 small blue macaws, 1 green Amazon parrot, and 2 yellow-green Amazon parrots. The last two birds fell ill in December, one about December 8th and the other about December 17th. Both birds were in the same cage, but were separated a few days after the first became ill. The latter bird died after some days' illness, and the remaining one succumbed about two weeks later. The parrot that first fell ill was not well from the start, but appeared to recover after a week or so, although the gardener was of the opinion that it was never quite healthy. During the period of acute illness the parrots suffered from diarrhoea, swollen eyes, ruffled feathers, loss of appetite, and inertia.

C. L. fell ill on December [illegible] and S. R. a few days later. Both fed the birds, but the parrots were not taken from their cage, and there was no [illegible] beak feeding. Both these patients recovered, and their illness was only moderately severe, although quite typical. These cases are of special interest in that the parrots were in this country at least three months before becoming really ill and infecting man. The dealer stated that they were in England for three months before purchase, thus making the total period since importation six months.

CASE 1.

C. L., male, aged 70, became unwell on December 17th. He was unduly tired, and slightly nauseated, but went to town as usual on that day and on the next two days. On December 19th he came home early from business because he felt faint and ill, and vomited. On December 20th and 21st he felt very unwell and nauseated, was drowsy, and slept a good deal. When seen on December 22nd he looked ill and thin, his tongue was furred, and he complained very much of nausea, headache, and a feeling of lassitude. He had a slight cough, but stated that this was not unusual; there was some thick muco-purulent expectoration. His temperature was 102° F., and his pulse 80, regular, and very soft, the systolic blood pressure being only 125 mm. Hg, and the respirations were 25. On examination of his chest the breath sounds at the right base behind were a little weaker than on the opposite side, and there were a few coarse crepitations. The abdomen was soft and normal, no enlargement of the spleen or liver could be detected, and no spots or skin eruption were seen.

On December 26th his temperature fell by lysis, and remained normal for four days, after which there was a slight recrudescence of his symptoms, the temperature again rising to 101° F., when he complained of a little pain in the right lower axillary region, but no physical sign could be discovered in his chest to account for this. Two days later the temperature again became normal, after which he entered upon convalescence.

Agglutination tests on January 2nd were negative for typhoid, paratyphoid A and B, *B. aertrycke*, and *B. enteritidis*.

CASE 2.

S. R., male, aged 48, felt unwell on December 18th, but had no definite symptoms. On December 20th he began to shiver, and thought he was about to have another attack of malaria, from which he had suffered since the war. He vomited several times and sweated. A profuse epistaxis occurred on December 21st, and lasted on and off for a few days. His temperature was 102.2° F., pulse rate 100, respiration rate 26. He was given large doses of quinine. The vomiting and shivering persisted for a few days. The quinine appeared to be without effect, the temperature remaining high. It was noticed that the pulse was relatively slow.

After the first week the patient was still feeling very ill, and complained of severe headaches. Delirium was present at night. The quinine was discontinued. At the end of the first week a slight, dry, irritating cough developed. On December 28th crepitations were present at the base of both lungs, and the next day the patient was removed to hospital. Constipation had been troublesome throughout the illness.

On examination in hospital, on December 31st, the patient appeared dull and lethargic. He responded intelligently to questions, but only after an appreciable latent period. His temperature was 102° F., pulse rate 88, respiration rate 24. His pulse was regular, and of moderate volume and tension. His tongue was coated and his abdomen distended. The spleen was not palpable. The lung signs had almost disappeared, and there was nothing abnormal in the heart or nervous system. In the evening of December 31st six red spots were seen on the chest and abdomen, a few more appeared on the back the next day, but they all disappeared within five days. The spots were about 2 to 4 mm. in diameter, the centre of them being slightly raised and papular. They faded on pressure, but on rubbing the finger across repeatedly they became more prominent, and were seen to be surrounded by a white halo, with a further thin red line bounding this like a planet.

On January 22nd the patient was still dull and apathetic. Slight cough had persisted; headache was diminishing; the abdomen was still distended. The next day the temperature began to fall by lysis, and on January 5th the patient was greatly improved, being quite bright and intelligent, and responded rapidly to questions in a manner that contrasted markedly with his former condition. He made a slow but uninterrupted recovery.

On January 3rd agglutination tests were negative to paratyphoid A and B, *B. aertrycke*, and *B. enteritidis*, but gave a partial agglutination to typhoid (1 in 64). This was probably due to the T.A.B. inoculations that the patient had received during the war. Blood cultures were negative.

CASE G. (London, W.).

This case is of very great interest in that the history of the parrot is known from the time it was caught in its native habitat, and because the evidence strongly favours the view that the bird was a carrier of the disease after

eight months' residence in this country. The parrot was a grey one, caught fourteen months previously on the Gold Coast of Africa. The bird was ill when caught, and took some weeks to recover. It was subsequently apparently quite well, and was brought to England by the owner in May, 1929. While in this country the parrot showed no signs of illness, except for transient attacks of mild diarrhoea, which were attributed to periods of injudicious feeding.

The patient was one day playfully protruding her tongue at the parrot, when the latter caught the tongue in its beak and held it tight for some seconds. The tongue was sore some days after this, but the patient became really ill ten days after this incident, and ran the course of a classical case of psittacosis. She eventually recovered after a very severe illness.

It is interesting to note that the parrot had been petted and played with by several members of the household for some time. It would thus appear that the contact in the case of carrier parrots must be of a much more intimate nature to transmit infection to man than is the case with recently imported sick birds.

Description of Illness.

L. S., female, aged 44, felt unwell on January 19th and complained of pains all over the body. She tried to relieve "the aching in every limb" by using liniment. The next day she remained in bed, with a very severe headache. She felt very weak, and sweated profusely and shivered at intervals. During the next few days her condition gradually became worse. Drowsiness and photophobia were present.

On January 22nd her doctor found the temperature to be 102° F., respiration normal, and pulse rate only slightly raised. On January 26th a dry cough developed, and a few moist sounds were found at the bases of both lungs. About that time two rose spots appeared on the abdomen, and persisted for a few days. Constipation was troublesome.

The tongue had been painful and sore from the first, but on January 28th the lips began to swell. This classical sign persisted for about four days, and then gradually disappeared. She was admitted to hospital on January 30th in a very collapsed condition. Her temperature was 103° F., pulse rate 100, and respiration rate 28. The patient lay quietly in bed, with eyes closed, pallid countenance, and well-marked peribuccal oedema. Moist sounds were present at the base of the right lung. The abdomen was distended, and the spleen was not palpable. During the next few days the hard, dry cough became very troublesome, and paroxysms of coughing left her very exhausted. On February 3rd she was very drowsy and collapsed, and it was doubtful whether she recognized people at the bedside.

On February 5th the temperature fell by lysis to subnormal. For some days after this the patient's condition showed no improvement, and the moist sounds were still present at the base of the right lung. From about February 10th she gradually improved, and on February 20th was sitting up in bed, talking cheerfully, although far from strong. The patient had no recollection of the greater part of her illness.

Agglutination tests on the eleventh day of the illness were negative to typhoid, paratyphoid A and B, and *B. aertrycke*. A blood count on that day showed: erythrocytes 4,600,000 per c.mm.; haemoglobin 63 per cent.; colour index 0.7; leucocytes 6,800 per c.mm.; polymorphs 77.5 per cent., eosinophils 0.5 per cent., small lymphocytes 11.5 per cent., large lymphocytes 2 per cent., large hyalines 8 per cent., transitional neutrophils 0.5 per cent.

CASE H. (Edmonton, London.)

This case is of interest in that the parrot was a grey African one. It was purchased from a shop in Camden Town on December 24th. It was never well, and, being suspected by the people themselves as the cause of the illness, was taken back to the shop on January 14th. The patient was taken ill about January 4th. She was the only person in the house who looked after the parrot, feeding it and cleaning the cage. There was no mouth-to-beak feeding. The patient recovered after a severe illness.

Description of Illness.

M. S., female, aged 52, was taken really ill on January 11th, but for about a week previous to this she felt unwell. On January 11th she began to shiver uncontrollably. In spite of sitting near the fire, hot drinks, hot-water bottles, and taking to bed, she remained shivering for twenty-four hours. She had a very severe generalized headache, pains all over the body, anorexia, and vague abdominal pains. She had no epistaxis. The bowels were kept open by a daily enema. A troublesome cough with copious purulent grey sputum was present from the first. The sputum was never rusty.

On January 15th some moist crepitations and dullness were present in the left posterior axilla and upper lobe. The temperature ranged from 101° to 103° F., with slight morning remissions. The respiration rate was about 28, rarely above 32, and the pulse rate was about 100. About this time the patient became drowsy and reluctant to open her eyes. On January 22nd the patient looked ill, weak, and collapsed. Her speech was quite lucid, but it was obviously an effort for her to talk or to move. The cheeks were flushed, and herpes was present on the lips. There was no marked respiratory distress. The respiration rate was 30, the pulse rate 100, and the temperature 101° F. The pulse was feeble, easily compressed, and of dicrotic character. There was a systolic murmur at the mitral area. There was no marked dullness, but some crepitations were still present in the left lung. The abdomen was slightly distended, and the spleen was not palpable.

Agglutination tests on January 22nd were completely negative to typhoid, paratyphoid A, and *B. aertrycke*, but gave a slight partial reaction to paratyphoid B (1 in 64).

CASE J. (South Woodford, London.)

In this case the parrot was a green Amazon, purchased on November 27th from a hawker, who obtained the bird from a sailor at the docks. In the first week of December the bird was obviously ill, with ruffled feathers, diarrhoea, and frothing at the beak; it died on December 12th. The patient looked after the bird, and was himself taken ill on December 17th. He eventually recovered after a severe illness.

Description of Illness.

On December 17th A. D., male, aged 60, began to "feel queer," and after a few days of gradually increasing lassitude and chilliness took to bed. Frontal headache, which began gradually, soon became severe. On December 21st he complained of a "woolly" feeling in the ears. He had a severe continuous frontal headache, and in addition lancinating neuralgic pain over the top of the cranium, with superficial tenderness. The morning temperature was 101.4° F. and evening temperature 101.8° F. The tongue was thickly furred, and there were a few "pinhead" ulcers on the floor of the mouth, with slight general injection of the fauces. On examination nothing abnormal could be detected in the chest or abdomen, the spleen was not palpable. Examination of the central nervous system was normal.

During the following ten days his temperature rose gradually, the morning and evening temperatures showing little difference. The highest temperature recorded was 103.4° F. on the fourteenth day of his illness. The headache was very persistent. There was slight mental wandering, but a marked feature was apathy and somnolence. He was easily roused, but dozed off again at once.

On January 1st (fifteenth day of illness) a slight cough appeared, and during the next two days a very small quantity of blood-stained sputum was expectorated. Fine crepitations were heard at the base of the right lung. On January 2nd a papular rash, very like measles in appearance, appeared over the extensor surfaces of both elbows and knees, and over the sacrum. This rash caused no inconvenience, and disappeared in a few days. The chest signs and symptoms had all gone by January 4th, and from this date the temperature fell by lysis and became normal on January 8th (twenty-third day of illness). With the fall in temperature the patient's condition rapidly improved, the somnolence disappeared, and on January 15th he was dressed and able to walk downstairs. Throughout his illness the bowels acted each *morning* after a dose of magnesia. The pulse rate was never more than 100.

Agglutination tests on December 31st were negative to typhoid, paratyphoid A and B, *B. aertrycke*, and *B. enteritidis*.

CASE K. (Basingstoke.)

A green Amazon parrot was bought from a London store on November 2nd. It was, however, soon seen to be ill, and was returned on November 26th, dying a few days later. The owner at first used gloves when handling the bird for fear of being bitten. Towards the end the gloves were discarded, and the patient was known to have stroked the parrot's breast, etc. He was taken ill on December 6th, and recovered after a very severe illness, at one stage of which it appeared that he would die.

Description of Illness.

C. B., male, aged 50, was taken ill on December 6th, with general malaise and pains in the limbs suggestive of influenza. Within the next few days he developed a very severe headache, which prevented sleep, and an annoying dry cough. He vomited on two occasions. The stools were not abnormal. When seen on December 18th his temperature was 103° F., pulse rate 100,

and respiration rate 42. His mind was quite clear. He had some red spots on his abdomen not unlike those that occur in typhoid fever. He had the physical signs of broncho-pneumonia. Agglutination tests at this time were all negative. For many days the patient was so ill that there was little hope of his recovery. After twenty-one days the temperature fell by lysis, and was normal on the twenty-fifth day of the illness. During convalescence thrombosis of the right femoral vein occurred with resulting oedema of the leg. This has gradually improved.

CASE L. (Willesborough, Kent.)

A green Amazon parrot was bought from a large London store about the beginning of December. It was ill from the start, and died on January 12th. The patient was taken ill on December 23rd, and eventually recovered from a very severe illness, during which he nearly died. He was known to have touched the bird and cleaned the cage.

Description of Illness.

T. H., male, aged 45, was taken ill on December 23rd, with headache and general malaise. On December 26th he was seen by his doctor, and found to have a temperature of 104° F., pulse rate 90, and respiration rate 26. He was then complaining of severe headache and backache. His throat was red and his tongue coated, but there were no other physical signs. The next day the patient became rather restless, and was troubled by constipation and abdominal distension. On December 29th S.U.P. 36 was given without any appreciable result. On the following day the patient was rather delirious, twitching and plucking at the bedclothes. A dry cough developed, and a few scattered sibilant rhonchi could now be heard in the lungs. The next day (eighth day) a semi-stuporose condition was marked, with intermittent complaints of a severe headache. A further injection of S.U.P. 36 produced no improvement. On January 4th some crepitations were present at the base of both lungs. The abdomen was still markedly distended. The spleen was never palpable. In spite of the paucity of physical signs in the lungs and the absence of any marked pulmonary symptoms the respirations were raised to 35 or 40 during the second week of the illness. On January 10th the temperature began to fall by lysis, and the patient gradually recovered from what was a very severe illness.

Agglutination tests to typhoid and paratyphoid A and B were negative on the eleventh and sixteenth days of the illness.

CASE M. (Norfolk.)

This case is of interest in that the birds apparently responsible were budgerigars. They were bought in a London shop, and arrived at the patient's house on January 11th, 1930. The next morning both birds seemed in good health, but at 12.30 o'clock one of them was found dead in the cage. The dead bird was handled by the patient, and put away for some days. She then again handled the dead bird in packing it for its dispatch to the London shop where it was bought. The body is said to have been examined by a veterinary surgeon, who said it had died from "inflammation of the bowels from cold." The patient fell ill on January 26th, and recovered after three weeks' illness.

Description of Illness.

E. P., female, aged 52, first felt ill on January 26th, when she complained of very severe headache and "sore scalp." On February 5th her husband noticed that she was short of breath while lying in bed; she got up the next morning and went about her duties, but she felt very ill, and was unable to stand at her work. On February 7th she was first seen by her doctor. Her temperature was 104° F., and pulse rate 96. She complained of intense frontal headache, pain in the back, and cough, but had no obvious dyspnoea. The tongue was dry and furred. There was slight diarrhoea. A few rhonchi and crepitations were audible over the right lower lobe. There was slight albuminuria, but no haematuria.

On February 9th she had a definite epistaxis. She then complained of headache, cough, and abdominal distension. Agglutination tests were negative for typhoid and paratyphoid A and B. Blood films showed nothing abnormal. A catheter specimen of urine showed only a cloud of albumin and no deposit.

On February 12th the patient was seen in consultation. On this day her temperature was 103.8° F., pulse rate 106, and respiration rate 28. She was pale in colour and mentally quite rational, though at times she had been delirious. The tongue was dry and covered with a brown fur. The heart was clear. The percussion note was impaired: breath sounds were vesicular, and crepitations were audible over the middle and lower lobes of the right lung. The abdomen showed no distension, and the liver and spleen were not palpable. No rose-coloured spots were visible. Agglutination tests were negative for typhoid, paratyphoid A and B, and *B. aertrycke*.

A blood count showed red cells 4,000,000 per c.mm.; haemoglobin 80 per cent.; colour index 1.0; there was no apparent increase in the total white cell count; polymorphs 75 per cent., lymphocytes 23 per cent., eosinophils 1 per cent., transitional cells 1 per cent.

On February 18th the patient was much better, and her temperature had come down to normal.

CASE N. (London.)

This is not one of our 27 cases in which there has been definite association with parrots or budgerigars. No contact with any bird could be traced in this case, but the clinical picture closely resembled that of psittacosis. Although we believe the etiological association with sick parrots to be definitely established with regard to human psittacosis, we nevertheless consider that this case may prove of some interest. Leichtenstern described similar cases, sometimes several in one household, occurring in Cologne in 1898 at the same time as the psittacosis epidemic.

Description of Illness.

G. C., aged 35, fell ill on January 24th with general malaise, aching in all her limbs, severe headache, and excessive perspiration. The temperature on the first day of the illness was 103.5° F., pulse rate 84, and respiration rate 26. On January 26th she complained of abdominal pain and vomited a few times. A surgical opinion was sought, but it was decided that there was no definite evidence of an acute abdominal lesion. A slight dry cough was present, and a few crepitations were heard at the right base. The temperature remained between 103° and 104° F. during the first week, with very slight morning remissions, the pulse was relatively slow (80), and respirations were not raised. At the end of the week there were signs of consolidation at the right base, respirations began to increase, but there was no sputum. During the second week the patient was drowsy and collapsed. The temperature remained high, with occasional remissions to 101° F., the respirations varied between 28 and 40 to the minute, the pulse remaining slow. When seen on February 6th the patient appeared to be in a typhoid state with muttering delirium. The lung signs were beginning to clear. There had been diarrhoea during the last few days. At the beginning of the third week the temperature began to fall by lysis, and the general condition appeared to improve. On February 12th, however, the patient was still very ill, collapsed, and completely apathetic. Moist sounds were heard at the base of the right lung. She gradually improved during the next week, the temperature, pulse, and respirations remaining normal. On February 20th she had a relapse, the temperature beginning to rise, and the patient becoming again mentally dull with nocturnal delirium. A trace of albumin was present in an alkaline urine. After a week the temperature began to fall again by lysis.

Agglutination tests were negative to typhoid and paratyphoid A and B in the second week of the illness, and these were repeated on February 12th (also with *B. aertrycke*), with similar negative results.

CLINICAL FEATURES.

(a) IN PREVIOUS EPIDEMICS.

Ritter[1] (1880) described his cases as "pneumotyphus." The onset was like that of an acute fever, with great exhaustion of the nervous system, high fever, and enlarged spleen. Bronchitis developed in the second week, and progressed to lobular pneumonia. Epistaxis and herpes occurred in some cases; meteorism, constipation, and fall of temperature by lysis were other features. One patient had roseola. He thought that the incubation period was nine to fourteen days, and that the disease was not contagious from man to man. When the patient recovered, convalescence occurred in the third or fourth week.

Dubief[4] (1892) gave an account of the clinical picture in the Paris epidemics.

"Its onset is insidious, simulating typhoid fever or influenza. The initial shivering, so characteristic of sharp, straightforward pneumonia, does not occur except when a late pneumonia sets in as a complication. The real characteristic of this severe infectious malady is the complete prostration in which the sick people are plunged. After a varying period of a typhoidal state there usually appeared a pneumonia, with or without an initial shivering—a pneumonia which often causes the death of the patient. Swelling of the lips may occur where there has been mouth-to-beak feeding."

In 1906, reviewing the past epidemics, Gilbert and Fournier[8] wrote as follows:

"It is in the nature of a general infective malady, allied to typhoid, in the course of which severe pulmonary complications show themselves. The inoculation period is eight or nine days. Then the signs of invasion commence, analogous to those of typhoid: malaise, collapse, anorexia, intense headache, epistaxis,

nausea, vomiting, slight diarrhœa, shivering; quinsy, stomatitis with false membrane, and peribuccal œdema have sometimes been noticed. In four or five days or less the temperature reaches 39°, 40°, or 41° C., and maintains itself at this level throughout the illness without pronounced morning recurrences. Great thirst, nausea, and vomiting are present, sometimes incessant; intestinal troubles are often almost absent. The abdomen is somewhat distended, and constipation obstinate. The urine is febrile. The patient is collapsed, often without stupor, but often, on the contrary, with profound prostration, accompanied by delirium. The nervous troubles are most pronounced with the appearance of pulmonary complications: general bronchitis with congestion of the bases, pneumonia, broncho-pneumonia, with or without pleurisy. These features are almost constant, and by their severity and gravity dominate the clinical picture. In fact, it is often to the pulmonary complications and their effect on the heart and circulation that death is due. In the latter case, after a recrudescence of the fever (41° C. or more) and some nervous phenomena (hallucinations, carphology, muscular contractions), the patient is seized with extreme dyspnœa, and falls into a terminal coma. Death usually occurs in the second or third week. When recovery is going to take place the symptoms decline in severity after eight or ten days, and convalescence sets in. In four or five days the temperature has returned to normal, but the convalescence is always lengthy. Benign and attenuated forms have been noted, especially in children and young adults, with recovery in a week or so. If one excludes the benign forms the prognosis is always serious. Death follows in a third of the cases. Middle and especially old age, and organic lesions, such as chronic heart disease, nephritis, obesity, and diabetes, are the principal bad factors in the prognosis. The diagnosis of psittacosis would often prove difficult without etiological information and the epidemiological character of the illness. Transmission from man to man has been cited by Dujardin-Beaumetz, Dubief, and Nicolle, but this is much more rare than transmission from parrot to man."

Of the Pennsylvania epidemic (1917) McClintock[12] writes:

"These cases were variously diagnosed as influenza, pneumonia, and very often as typhoid fever. But in all an element of uncertainty was strong. Many of the symptoms of one or all of these diseases were present, but the grouping and degree of intensity of the different symptoms differed from those of any disease so far observed in this community. Although certain cases fitted exactly the accepted symptom-grouping of this disease as a whole, the clinical picture in this epidemic varied more than in those previously described, and the mortality was distinctly lower, not above 5 per cent.

"In this epidemic the incubation period appeared to be about ten days. The duration of the disease varied from one to four weeks. Three groups of cases were easily differentiated. In all three a terrific headache was a common symptom; this was associated with a most profound prostration. The pulse rate was not often above 100. The temperature curves were often irregular; most frequently they simulated those of typhoid fever. The leucocytes when counted were nearly normal in number, and all Widal tests taken were negative. The majority of cases resembled either influenza, with rhinitis, conjunctivitis, and cough; pneumonia with a high sustained fever, but a nearly normal pulse rate; or typhoid fever, both with and without a splenic tumour, and without rose spots. Some showed a combination of well-marked symptoms, involving the entire respiratory and gastro-intestinal tracts. In all cases there appeared to be some involvement, however slight, of the upper respiratory tract, the lungs, and the gastro-intestinal tract. A peculiar odour, resembling that observed in typhoid, pervaded the surroundings of these patients. The lung signs were very baffling, exhibiting scattered areas of dullness, often wandering, with moist rales, and frequently without any abnormality in the breath sounds. The lung signs rarely balanced one another, rarely were they typically pneumonic."

In Beddoes's[14] cases the symptoms were those of pneumonia, with, however, very marked prostration. The expectoration was slight, and not coloured by blood pigments.

In Gulland's[15] cases lung involvement was a marked feature, although the cough was slight and sputum negligible. In the first case the illness started with a sudden pain in the side, and in the second case with a rigor. From the latter case 10 oz. of clear sterile fluid was withdrawn from the pleural cavity. The temperature rose in step fashion and fell by lysis. A depressed mental state was present in both cases.

Stolkind's[16] second case was fatal, and at necropsy pneumonia of the right lung and lower half of the left lung was found.

In Thomson's[17] cases (first series) the development of an enlarged, painful parotid gland occurred in one patient. Of his four cases, two were fatal.

(b) PRESENT SERIES.

The symptomatology and physical signs in our series of cases corresponded closely with the classical description of Gilbert and Fournier.[4] In many respects there was a marked resemblance to typhoid fever, but pulmonary involvement of varying degree occurred in every case. The illness usually lasted two to three weeks, during which time the patient's condition was often critical.

Incubation Period.

In eight cases the incubation period could be determined with some degree of certainty. It varied between eight and thirteen days. This is in agreement with the observations of Ritter,[1] 1880 (nine to fourteen days), Dubief,[3] 1893 (nine days), Gilbert and Fournier,[4] 1896 (eight to nine days), and McClintock[12] of Pennsylvania, 1917 (seven to twelve days).

Onset.

The onset was sudden in most cases, the patient taking to bed within a few hours of the initial symptoms. In a few instances, however, a mild degree of malaise occurred for some days, during which time the patient continued with his normal occupation.

The initial symptoms were usually headache and malaise. These were often associated with, or soon followed by, shivering, generalized pains in all the limbs, backache, abdominal pain, anorexia, nausea, vomiting, sore throat, sweating, and epistaxis. Conjunctivitis occurred but rarely. The headache was usually very severe, and was not ameliorated to any extent by analgesics. It was most commonly situated in the frontal region, but was sometimes parietal, occipital, or generalized. One patient described her headache as "throbbing and sore, as if someone were beating or scraping the top of my head." Increasing in severity during the first few days, the headache persisted for about ten days and then tended to disappear.

The shivering attacks or rigors were not constant in their time of onset. Sometimes they occurred as an initial or early symptom, whereas in other cases they coincided with the beginning of pulmonary involvement (as described by Dubief). In one case rigors occurred on the fourth, fifth, and tenth days. Although sometimes slight and of short duration in other cases they were very severe and lasted for twenty-four hours.

Sore throats were not infrequent, the fauces and soft palate being red and sometimes covered by a yellowish exudate. In only one case was the classical sign of peribuccal œdema observed, and that occurred in a patient who was actually bitten on the tongue by a parrot. Sordes of the lips and herpes labialis were present in some cases.

Epistaxis occurred in six cases, usually within the first few days, and was often profuse. In one case it started on the fourth day and recurred every day in large amounts until the ninth day.

Rose spots were observed in five cases, usually appearing about the end of the first week. Their characteristics are given with the detailed description of the cases.

Respiratory System.

The lungs were involved in all cases. A cough developed usually towards the end of the first week, although in some cases it was an initial symptom, and in others it did not appear before the second week. Usually the cough was a dry one, but in several of the cases particularly those of Group B, there was a considerable quantity of muco-purulent sputum. In only one case was there typical rusty sputum, and that occurred in the late stages of a fatal case. The cough was often troublesome and intractable, paroxysms of coughing shaking the whole body, aggravating the headache, preventing sleep and leaving the patient very exhausted.

In spite of pulmonary symptoms and signs the respirations were usually not markedly quickened, although in fatal cases, and in some that recovered, respirations were raised to 40 or more a minute.

The signs in the lungs were variable. As a rule they began with a few moist sounds at one or both bases. In some cases there were, in addition, rhonchi scattered

throughout the lungs. The crepitations usually appeared about the sixth to tenth day, and gradually increased in number. During the second week a patch of consolidation not infrequently developed near the angle of one scapula. In some cases this area appeared to spread so as to involve the whole of one lower lobe, or other small areas of consolidation might be present at the bases of both lungs. The physical signs were occasionally those of a wandering pneumonia. In many cases the signs did not progress beyond the presence of moist sounds, and in two cases the pulmonary signs and symptoms were of the slightest. In one fatal case there was a slightly turbid pleural effusion and in another a pleural rub was heard. The crepitations at the bases of the lungs often persisted for several days after the temperature was normal. Cyanosis was present in those cases where the lungs were extremely involved, especially in the fatal cases.

Nervous System.

Photophobia was noted in several cases as an early symptom, one of the patients stating that she saw double when looking at objects in bright light. Some of the patients insisted on the blinds being drawn, and others wore eyeshades. A typhoid-like state developed towards the end of the first week. The patients usually lay quite still in bed in a collapsed immobile condition. They were often very sleepy after the first few days, finding difficulty in keeping their eyes open; later they became stuporose and even semi-conscious, some of the fatal cases falling into deep coma. They appeared to be quite oblivious to their surroundings, often failed to recognize their friends, were roused with varying degrees of difficulty, and soon lapsed into their previous state. Alternating with periods of somnolence there sometimes occurred phases of great excitement and restlessness. One patient became very aggressive and struggled to get out bed. Another, in a nursing home, actually left her bed and rang the bell without knowing why she did so. Delirium was common, and worse at night. Two patients complained that they unsuccessfully tried to keep awake because if they fell asleep for a few minutes they awoke muttering nonsense. Disorientation of time and place frequently occurred.

Examination was greatly resented by some, whereas others were completely uninterested in what was happening. The patients often remained in a collapsed and stuporose condition for several days after the temperature had fallen to normal. An interesting feature was the complete failure of many of the patients to remember the greater part of their illness.

Gastro-intestinal Symptoms.

Anorexia and nausea were frequent early symptoms. In some cases vomiting was present, and although usually occurring but once or twice, was sometimes incessant. Initial abdominal pain occurred in a few cases, the doctor in two instances considering the possibility of appendicitis.

Constipation was present, and troublesome, in the majority of the cases, the abdomen being very distended. Meteorism was relieved by turpentine enemata and the passage of flatus. In a few cases diarrhoea occurred at some period during the illness, but only for a few days. There were no signs of intestinal haemorrhage or of perforation. The spleen was not palpable in any of our cases.

Cardio-vascular System.

In the majority of cases the rate of the pulse was markedly slow in relation to the temperature. Thus with a temperature of 103° F. the pulse was often less than 100. In those with extensive involvement of the lungs and in all fatal cases the pulse became rapid and feeble. There were no signs of importance in the heart, although a systolic murmur might be present in the apical region. In two cases thrombosis of the femoral vein occurred during convalescence.

Pyrexia.

The temperature was generally very high (about 103° F.) from the outset. There was usually no definite evidence of a step-ladder rise as in typhoid. The temperature was maintained at a high level for about two weeks, when it usually fell by lysis. In many cases there was hardly any remission of temperature during the mornings, but in others the pyrexia was of the swinging variety with morning remissions.

In the convalescence period the temperature was often subnormal (97° F.). In the fatal cases the temperature tended to remain high throughout. Convalescence was often slow and tedious. In a few cases there were definite relapses similar to those occurring in typhoid fever.

Diagnosis.

A typhoid-like illness, with pulmonary involvement and negative agglutinations, is very suggestive of psittacosis, especially if there is a clear history of association with a sick parrot.

Prognosis.

The mortality in this series was approximately 20 per cent. The ages of those that died were 60, 53, 52, 30, and 18. One of the chief factors in the prognosis appears to be the extent of pulmonary involvement and associated secondary infection. In all the fatal cases there was much respiratory distress, cyanosis, and profound toxaemia. These features were especially marked in the Barking group B, where 3 out of 5 died.

Mode of Infection.

Of our 27 cases, 25 were apparently caused by green Amazon parrots from South America. In 23 cases the birds were very recently imported, and were more or less ill from the start. In two cases the parrot concerned had been in the country for a few months.

Of the two grey African parrots, one was recently imported and was obviously sick. The other had been in this country for eight months, was apparently in good health, and must be regarded as a carrier of the disease. In this case the contact necessary for transmission of the disease had to be most intimate—biting of the patient's tongue. In those cases where the bird was itself obviously ill, contact was often of the slightest, and in one case, where the patient merely sat in the room from which the dead bird had recently been removed, it would seem that the infecting agent had been disseminated throughout the room.

Man-to-Man Infection.

We consider this the probable mode of infection in two of our cases. Dujardin-Beaumetz[4] (1892) and Nicolle[7] (1898) gave some evidence of man-to-man infection, the latter citing the case of a nurse. Banti and others,[9] in describing the Florence epidemic of 1894–95, state: "As for contagion, direct carrying from person to person, there were incontestable if rare examples." Leichtenstern[11] describes a definite case in Cologne (1898) where the patient had been in contact with the parrot at another house, and the nurse, who apparently contracted the disease from the patient, had never been in the same house as the parrot. Other cases (for example, medical attendant) have come to our knowledge but are not in our series of cases. Man-to-man infection must be regarded as a rare but possible mode of contracting psittacosis.

BACTERIOLOGY AND SEROLOGY.

Ritter[1] (1880) reports that some of the parrots concerned in the epidemic died and the remainder were killed. All the birds were examined after death by Professor Eberth with negative findings.

In 1883 Wolff[22] examined the bodies of twelve grey parrots from the Guinea Coast with a view to explaining the immense mortality in parrots brought thence to Germany, and found micrococci in great numbers. Eberth[23] had similar findings with a grey parrot.

In 1892 Nocard[4] isolated a bacillus (*B. psittacosis*) from a parrot. It is of interest to note that Nocard was unable to secure any of the birds that caused the Paris epidemic. He writes:

"In spite of my efforts I have not been able to procure, dead or alive, one of the many sick parrots imported by Dubois and Marion, and I do not know that others have been more fortunate; at least no one has published clinical observations or the results

of a complete and methodical necropsy on a single one of these parrots. I have been able, however, to make some interesting researches, thanks to the kindness of M. Besançon, who has been good enough to put at my disposal a large packet of wings belonging to parrots that died on the voyage from Buenos Aires to Havre. . . . Before throwing the corpses into the sea Marion deprived them of their wings, which he carefully packed after having dried them."

Nocard examined them four months after this, and obtained from the marrow in pure culture an organism he described as follows:

"A short bacterium, rather thick, with rounded extremities, both acrobic and anaerobic, extremely motile; the bacterium develops rapidly over the greater part of the media, solid or liquid, used in microbiology, provided that the reaction of the medium is neutral or slightly alkaline; it is Gram-negative, does not liquefy gelatin, does not ferment lactose, does not coagulate milk. It is pathogenic for the pigeon, fowl, mouse, rabbit, and guinea-pig."

In 1896 Gilbert and Fournier[2] secured a parrot that had died of diarrhoea, and obtained Nocard's bacillus from the spleen, bone marrow, and intestine. In the case of M. and Mme X, who died of psittacosis, Gilbert and Fournier examined the sputum, and also the blood obtained by pricking the finger. The sputum contained pneumococci and streptococci, but not Nocard's bacillus. Blood culture was sterile. Blood culture (from the vein) in two other cases was also negative. In one of these cases pleural fluid and splenic puncture three days before death also gave sterile cultures. Blood from the heart of this patient (at necropsy) yielded a bacillus identical with that of Nocard. Gilbert and Fournier state that the bacillus of Nocard resembles that of Eberth, but it is clearly distinguished by the appearance of the culture on gelatin and on potato, and especially by its extreme virulence to laboratory animals, which are killed in twenty-four to forty-eight hours. Parrots may die ten to twelve hours after subcutaneous injection of two drops of broth culture. In *La Presse Médicale*, however, Gilbert and Fournier[4] wrote as follows:

"The morphology and biological properties of Nocard's bacillus enable us to suggest that this micro-organism is no other than a *coli* bacillus normally inhabiting the intestine of parrots and acquiring under unknown influences pathological properties. We have found in the intestines of normal parrots special varieties of para-*coli* bacilli, some of which approximate in character to the bacillus of Nocard."

They also noted that typhoid serum produced small agglutinations with Nocard's bacillus, but to a very much less degree than with typhoid bacillus. The serum of two patients, ill with psittacosis, did not produce any agglutination with *B. psittacosis* obtained from the parrots, or from the heart's blood of another fatal case (previously recorded). The patients were only in the fifth day of their illness.

In 1897 Sicard[3] examined two parrots that were the cause of a small epidemic, and had died. In the case of one of these birds he obtained *B. psittacosis* from the heart's blood and bone marrow, but it is interesting to note that he was unable to obtain the bacillus either from the blood or from the organs of the second parrot. He was equally unsuccessful with some small exotic birds that had been in contact with the parrots and that had died. As regards man, Sicard[3] had negative results from "the numerous and frequently repeated cultures made at the height of the fever and in the convalescent period, from the blood of the arm vein, from the spleen, from the lung, or from the urine and faeces of the very ill patients taken into hospital."

Sicard[3] also investigated the power of agglutination in man.

"The serum of the hospital patient was examined during the development of the illness, on the fifth day of the illness, then every second day, and during the convalescent period every four days. The serum of the other four patients was only taken twice, once during the period of the illness and once during convalescence. The suspected serum behaved towards *B. psittacosis* in the same manner as that of normal people, or of patients with other illnesses. There was produced under the influence of any human serum a physiological agglutination of this bacillus. This agglutination always exists at 1 in 5, is able to continue at 1 in 10, and in some cases at 1 in 20, and presents slight variations according to the culture employed. Those of M. Nocard and our own always appeared to agglutinate a little more than those of MM. Gilbert and Fournier. This agglutination, which occurs with a serum kept for some time, is often defective with fresh serum, and is then replaced totally, or in part, by a transformation into granules, without complete bacteriolysis."

Sicard[3] then investigated the bactericidal properties of the suspected serum with negative results.

"Tested with fourteen human serums, precipitation of bacilli occurred at the bottom of the tube. Microscopic examination showed numerous masses, often in long and flexible chains. The vitality of the bacilli was preserved, as well as their virulence, as was shown after twenty-four hours in agar by inoculation into mice. From the preventive point of view we have equally been unable to establish a difference of action between the suspected serum and other serums, which were injected into mice and sparrows twenty-four hours before their inoculation to *B. psittacosis*."

Nicolle[5] in 1898 reports as follows:

"We have not been able, in spite of all our efforts, to isolate the pathogenic microbe from the different products which have been sent us: blood of three patients, faeces of two, sputum of one. The necropsy of the parrot also gave negative results. In the case of one patient, attacked with a fatal form of the disease, the serum taken on the eighth day agglutinated *B. psittacosis* 1 in 50 and on the ninth day (when the patient was dying) the agglutinating power reached 1 in 60. The same serum has twice shown activity of 1 in 30 to typhoid bacilli, but no action on *B. coli*. The patient had never had typhoid fever.

"In the case of a second patient, severely attacked, but who recovered, the serum taken on the sixth day was without action on Nocard's bacillus, typhoid bacillus, and *Bacillus coli*; on the eleventh day it agglutinated *B. psittacosis* 1 in 10, but remained inactive towards the two other microbes. The blood of a third mild case examined on the sixth day, had no agglutinating power. Parrot's serum, obtained on the fifteenth day after its recovery, also gave negative results."

Gilbert and Fournier,[4] reviewing the situation in 1905, state:

"M. Nicolle has shown that the serum diagnosis of psittacosis is possible, the agglutinating power being relatively raised in one of his cases (1 in 50, 1 in 60) and feeble in another (1 in 10). But the agglutinating power is often wanting (Gilbert and Fournier, Sicard). . . . Do there exist other forms of psittacosis or other infective maladies of parrots transmissible to man and not having the bacillus of Nocard as pathogenic agent? This is quite possible. The bacillus of Nocard could not in some cases be recovered from the bodies of parrots which had apparently been the focus of spread of small limited epidemics; but these facts are still badly defined clinically and bacteriologically; it suffices to note them."

In 1904 Vickery and Richardson[12] recorded that the serum of their patients was negative to typhoid and paratyphoid bacilli, and to a streptococcus recovered from the spleen of the parrot. Apart from the latter, which they regarded as a contamination, all cultures from the organs of the dead parrot were negative. No bacteriological or serological findings are reported in the cases of Beddoes (1914), Gulland (1924), or Stolkind (1927).

In 1917, when studying an epidemic in Pennsylvania, McClintock[13] found a variety of organisms, and suggested a pleomorphic nature of *B. psittacosis*. In 1920 Marrian Perry[14] obtained *B. psittacosis* from a grey touracon that had died, and by absorption and agglutination tests found that *B. psittacosis* was identical with *B. aertrycke* of the "Mutton" type. He quotes Bainbridge who came to a similar conclusion.

Thomson[15] (1929) records serological and bacteriological findings in one of his cases. The Widal test was positive to paratyphoid B 1 in 1,000. In the course of the illness the right parotid gland became swollen and painful, and a small quantity of blood-stained fluid was aspirated from it and culture media inoculated. Cultures gave a bacillus which was first Gram-positive, but after forty-eight hours' growth *in vitro* became completely Gram-negative. Thomson observes that the bacteriological report, "although it does not conform in every detail with some of the published accounts of *B. psittacosis*, nevertheless shows that it belongs to the same group of organisms, individual strains of which

are known to vary considerably in their behaviour in the laboratory." Thomson, however, does not regard the identity of the bacillus as established.

In view of the classical conceptions of the etiology of psittacosis, we approached our first case from the point of view of obtaining positive agglutination tests with *B. psittacosis*, and perhaps isolating the bacillus. Our results were completely negative, even after necropsy. This appeared to throw doubt on the diagnosis and to induce a sceptical attitude as to the question of parrot infection. A close study of all the available literature, however, brought out several important points: (1) There was the strongest circumstantial evidence in favour of parrots being the cause of psittacosis. (2) Several able investigators, Sicard[3] among others, had failed to obtain any evidence of positive agglutinations with typhoid, paratyphoid, and psittacosis bacilli in undoubted cases of the disease. The titre of agglutination in some of the Paris cases was of such an order as to have little or no significance. (3) Throughout half a century the alleged causative organism, *B. psittacosis*, had been isolated from a human being in only one case, and that at necropsy. This was done by Gilbert and Fournier,[6 7 8] who, when reviewing the whole subject at a later date (1906), themselves began to doubt its etiological significance. (4) The classical clinical descriptions corresponded so closely with our first case and the second member of this group (whom we had subsequently visited) that the diagnosis of psittacosis seemed without doubt.

It was in an endeavour to fit all these facts together that we conceived of the possible virus origin of the disease, and we were fortunate in securing the collaboration of Dr. S. P. Bedson and Dr. G. T. Western in investigating this point. Many of the results of the experimental investigations have already been published,[25] and we shall therefore not describe them in this paper. In brief, it may be stated that a filterable virus was isolated from parrots which had died of psittacosis and which had been responsible for cases of the disease in man. Further, citrated blood from human cases, although apparently sterile when tested culturally, produced the disease in every instance when inoculated into budgerigars. It has been seen from the detailed notes of our cases that negative blood cultures and negative agglutinations have been found in nearly all of them. It is true that the close similarity between many of the clinical features of psittacosis and those of typhoid fever might by analogy suggest a bacillary origin for the former, but a consideration of this question opens up a very wide field of inquiry. The London Hospital investigations offer strong evidence in favour of the virus origin of psittacosis, although this does not exclude the possibility of secondary infection with other organisms.

PATHOLOGICAL REPORTS BY PROFESSOR H. M. TURNBULL.

GROUP E, CASE 1.

Summary of Findings.—Thrombosis of pulmonary arteries. Haemorrhagic pneumonia. Septicaemia. Slight muco-purulent bronchitis. Diffluent, red septic spleen; iron pigment in spleen. Parenchymatous degeneration and post-mortem staining of myocardium, liver, and kidneys. Oedema of kidneys. Iron pigmentation of coeliac gland. Proteolysis and lipolysis of very adipose pancreas. Great central softening of suprarenal bodies. Emphysema of lungs; quiescent tuberculosis; pinhead fibro-caseous nodule in apex of upper lobe of right lung; pinhead calcareous nodule in lymphatic gland of tracheal bifurcation. Eight pigment calculi (largest 1.4 by 0.7 by 0.7 cm.) in gall-bladder. Foramen ovale closed. Moderate general atheroma. Numerous chylecysts in submucosa of jejunum; Peyer's patches small and inconspicuous. Fibrous obliteration of terminal 1.5 cm. of 11 cm. appendix. Sessile polyp (0.25 cm. diameter) in transverse colon. A few small (largest 0.15 cm.) internal haemorrhoids. Stout, grey-haired, well-developed man. Examination of brain not permitted.

Weights: Body, 82 kilograms (length 1.68 metres); liver, 1,417.5 grams; heart, 326 grams; kidneys, 290.6 grams; spleen, 177.2 grams; pancreas, 126.2 grams; suprarenal bodies, 11.2 grams.

Macroscopic Examination.

The necropsy was performed by Dr. A. B. Bratton. The body had not been placed in the freezing chambers, and there was moderate post-mo throughout. A portion of friable striated and 1 cm. in diameter, lay free in the pulmonary artery in the hilum of the upper lobe of the right lung; a fragment of similar clot, 2.5 cm. long and 0.7 cm. in diameter, lay in the pulmonary artery to the upper lobe of the left lung. There was no ante-mortem thrombus in the large veins of the neck, chest, and abdomen; incision of the limbs was purposely avoided, but the content of the subclavian and femoral veins was expressed and consisted of fluid blood. The most striking abnormality was the condition of the lungs. There was no free fluid in the pleural sacs. The lungs were voluminous and showed the characteristic appearances of hypertrophic emphysema. A thin layer of fibrin covered the lower part of the upper lobe of the left lung, and a layer of fibrin containing numerous red clots lay on the anterior surface of the lower lobe. The lower third to one-half of the outer surface of the upper lobe of the left lung, from a little below the apex to the tip of the lingula, was swollen and dark purple. It felt boggy and gave slight crepitation. The cut surface was deep red, and very slightly granular; blood and a few bubbles of air were alone expressed. On the cut surface of the rest of the upper lobe of the left lung were a few small areas of similar appearance, and yellow slime was expressed from some bronchi. The anterior surface of the lower lobe of the left lung was depressed and dark red, while the angle between the anterior and diaphragmatic surfaces was replaced by a thin, flabby, airless fringe. On section a smooth, deep red, largely airless zone (0.5 cm. deep) lay under the depression, and the fringe had a similar appearance. On pressure, yellow slime escaped from some of the bronchi in the depressed area, and in the remainder of the left lower lobe. Yellow slime was expressed from some bronchi in the right middle lobe. The lower lobe of the right lung resembled externally the lower part of the left upper lobe, being swollen and dark purple. The upper part felt less solid than the lower, and crepitated. The cut surface of the whole lobe was deep red. The upper part was very slightly granular, the lower part was more homogeneous and more granular, but the granulation was not conspicuous. The cut surface recalled that of the haemiolytic streptococcal pneumonia which was associated with influenza in 1918. Yellow slime was expressed from bronchi in the antero-inferior angle alone. A portion was removed from the posterior part of this lobe for bacteriological examination by Dr. G. T. Western. The abnormalities in other organs have been indicated in the summary. No evidence of inflammation could be detected in the intestines.

Microscopic Examination.

Portions were removed for microscopic examination from the swollen lower border and lingula of the upper lobe of the left lung, the upper and lower parts of the swollen lower lobe of the right lung, the collapsed zone beneath the pleura of the anterior surface of the lower lobe of the left lung, the spleen, the pancreas, and the pigmented coeliac gland.

The Lungs.—In the *upper part of the lower lobe of the right lung* all the vessels are greatly engorged. The walls of the bronchioles are intensely injected and are infiltrated with large mononuclear leucocytes, histiocytes, large and small lymphocytes, and a few neutrophil leucocytes. The lumen of one contains red corpuscles, a few desquamated epithelial cells, neutrophil leucocytes, and large mononuclear leucocytes. The others have an empty lumen, and have lost their epithelium. The respiratory bronchioles, alveolar passages, and infundibula almost all contain inflammatory exudate, but seldom appear completely filled by it. The few that are empty are dilated. Most contain neutrophil and large mononuclear leucocytes, red corpuscles, and desquamated epithelium. Some contain also a little bubbly coagulated albumin or a few threads of fibrin. In one area red corpuscles are very numerous, and here fibrinous and serous exudate are much more abundant, while leucocytes are relatively scanty. Changes in the epithelial lining of the affected air spaces are conspicuous. The epithelial cells are greatly enlarged, and have an abundant spongy basophil cytoplasm; the nuclear membrane, close net of chromatin threads, and large nodes are brightly stained. Several show karyokinetic figures. Small heaps of large cubical and rounded epithelial cells frequently lie upon the muscular wall of the respiratory bronchioles, while ribbons of large spindle cells lie upon or close to alveolar walls. Other epithelial cells have been desquamated and are rounded. The pleura is swollen by oedema and contains some haemorrhages.

In the *lingula of the upper lobe of the left lung* the infiltration of the walls of the bronchioles is greater and contains

more numerous neutrophil leucocytes. In *some* a deep zone of neutrophil and large mononuclear leucocytes raises the epithelial lining as a continuous sheet, in others the raised sheet is broken, and leucocytes have reached the lumen. The centres of the lumina are usually empty or nearly empty; one contains coagulated serum and a few leucocytes. The respiratory bronchioles, alveolar passages, and infundibula contain an infiltrate which in general resembles that in the previous section. The cellular infiltrate is, however, more abundant, filling and distending the spaces, and bubbly coagulated exudate is more frequent. The pulmonary arteries are greatly engorged, but are not thrombosed.

In the *posterior part of the lower border of the upper lobe of the left lung* a large bronchiole has great haemorrhage in its wall, the epithelium consists of a layer of flattened cells, the centre of the lumen is occupied by air, and the periphery by leucocytes, red corpuscles, necrosed cells, coagulated albumin, and a few filaments of fibrin. The respiratory bronchioles and alveolar passages contain an exudate similar to that in the infundibula, but many are greatly distended by air, the exudate being confined to the periphery of the lumen. The exudate is more abundant than in previous sections and distends the air spaces more. It consists mostly of coagulated albumin, but in places of fibrin. Red corpuscles are very numerous. They are more numerous in the fibrinous than in the serous exudate; groups of alveoli are crammed with red corpuscles. The cells seen in previous sections are present, but they form a relatively insignificant part of the exudate. Further, most of them are very degenerate, or are completely necrosed and represented by cytoplasmic spheres; some well-stained neutrophil leucocytes are, however, always present.

Hyaline thrombi are frequent in the engorged capillaries of the alveolar walls. Hyaline thrombus also lines or fills several small pulmonary arteries. Some larger pulmonary arteries show a peripheral layer of degenerate leucocytes; a few are filled with white thrombus. The pleura is congested, slightly infiltrated, and covered by a layer of fibrin.

In the *lower part of the lower lobe of the right lung* there are still respiratory bronchioles and alveolar passages distended by air, and occasional groups of alveoli which contain little or no exudate. The condition is very similar to that in the previous section, but fibrin containing many red corpuscles is now the predominant form of exudate, many alveoli are filled with red corpuscles, most of the alveolar capillaries contain hyaline thrombus, hyaline thrombus fills a great number of the smaller pulmonary arteries, and many large pulmonary arteries are occluded by white or mixed thrombus. Large bronchioles are lined by one or two layers of flattened spindle epithelial cells, and are filled with fibrin, ghosts of necrosed cells, a few red corpuscles, and scattered neutrophil leucocytes. There is great oedema of the pleura.

In the *anterior surface of the lower lobe of the left lung* there is a subpleural zone of collapse, which contains a few emphysematous areas. Beneath this there are small areas of collapse in a general emphysema. The tissue throughout is intensely engorged. In the subpleural zone there is an area in which the collapsed alveoli contain a few red cells and leucocytes, while a respiratory bronchiole shows a few leucocytes beneath its epithelium, and a few leucocytes and red corpuscles in the periphery of its lumen. The feature of this section is the presence within bronchioles and respiratory bronchioles of desquamated epithelium, a few large mononuclear and neutrophil leucocytes, and masses of bacteria. The bacteria are Gram-positive, and in less number negative, streptococci and staphylococci, and Gram-positive, long, stout bacilli. In the other portions of the lungs no organisms were found in sections stained with dilute carbol-fuchsin or by the Weigert-Gram method with neutral red.

The spleen was so diffluent at necropsy that the tissue in the microscopic sections is split into small fragments. It is impossible to differentiate the capillary veins from the pulp strands. The organ is engorged and infiltrated. Neutrophil leucocytes are numerous, but the feature of the infiltration is the great number of large mononuclear cells with deeply basophil cytoplasm (Unna-Pappenheim stain) and conspicuous nodes and nucleoli. Some of these cells have the clock-face nucleus of plasma cells, others contain karyokinetic figures. There is much haemosiderin, chiefly within cells. No micro-organisms were found in a section stained with dilute carbol-fuchsin.

The pancreas is very adipose. There is very extensive digestion of the glandular tissue and islands, and *much* lipolysis of the adjacent adipose tissue. The ducts contain digested desquamated epithelium, and sometimes also a little mucous coagulum. There is no cellular infiltration.

The coeliac gland shows areas in the adenoid tissue in which the walls of vessels have undergone great hyaline collagenous swelling, recent necrosis in the centres of many cortical nodules, and great sinus-catarrh. Most of the desquamated cells in the sinuses are large and necrosed. Many contain fine granules of a brown pigment that does not give an iron reaction, others contain large grains of haemosiderin. The sinuses also contain red corpuscles and numerous extracellular isotropic particles of brown-yellow haemosiderin, of which most are large, and fusiform or spherical.

Remarks.

The changes found at necropsy were those of a general infection, or bacteriaemia, associated with a peculiar inflammation of the lungs. No bacteria were found microscopically except numerous streptococci, staphylococci, and Gram-positive bacilli within bronchioles in one section of the lung.

The naked-eye and microscopic examinations showed that this bronchitis very rarely affected the portions of lung involved in the pneumonia. There can be no doubt that it was a terminal and independent muco-purulent bronchitis. The peculiar inflammation of the lung involved bronchioles, but it had not the appearance of a pneumonia secondary to bronchitis—that is to say, a broncho-pneumonia. The descriptions of the portions of lung examined microscopically have been set in the order of apparently progressive stages in the inflammation. Briefly, an intense engorgement, proliferation and desquamation of epithelium, leucocytic infiltration, and slight haemorrhage were followed by increasing haemorrhage, abundant serous and later fibrinous exudate, progressive degeneration and death of the earlier infiltrating cells, and an increasing thrombosis of capillaries, and small and large pulmonary arteries. The extent of the thrombosis in the severest expression, apparently the last stage, of the inflammation was most remarkable.

The portions of thrombi found in the pulmonary arteries in the hila of the upper lobes of the right and left lung had doubtless been formed within pulmonary arteries; no thrombosis was found in large veins of the systemic circulation.

The amount of haemosiderin in the spleen, and particularly in the coeliac gland, gave evidence of much destruction of haemoglobin, but laked red corpuscles were not seen. The characteristic of the inflammation of the spleen was the infiltration with large cells of lymphoblastic type.

The digestion of the pancreas, like the central softening of the suprarenal bodies, was doubtless due to autolysis in a severely infected cadaver that had not been placed in the freezing chambers. The preservation of the tissues in general, however, was shown by the micro-scope to be good, and much better than was expected from the appearance at necropsy.

GROUP B. CASES 1, 2, AND 4.

The microscopic examination of the material from these three cases has not yet been made. The necropsies were in general closely similar to that of Group E, Case 1. Terminal heart failure was shown by congestion and oedema of the liver and kidneys, and in Case 1 by oedema of the legs. Septicaemia was indicated by parenchymatous degeneration of the myocardium, liver, and kidneys, and by increased cellularity of the pulp of the spleen. The severest changes were in the lungs. A new feature was found by Dr. W. W. Woods in Case 2 in the form of focal areas of degeneration, haemorrhage, and rupture in the rectus abdominis muscle; and in Case 4 Dr. A. B. Bratton found focal haemorrhages in the rectus abdominis and the gluteus maximus.

Lungs.—The changes in the lungs were most advanced in Case 1. In the left lung the lower lobe and lower third of the upper lobe were conspicuously swollen and purple, while the remainder of the upper lobe was slightly swollen. The lower half of the lower lobe and the lingula of the upper lobe felt like liver, and on section showed an even, finely granular, pink cut surface. On pressure, very abundant frothy fluid exuded from the bronchioles. Excised portions just sank in water. Similar changes will be referred to as red hepatization. The remainder of the left lung felt boggy, with focal areas of firmer consistence.

When freshly cut the surface was very moist, or ran with water, showed slight speckles of aeration in a few small areas and faint granulation in larger patches, but for the most part appeared homogeneous, somewhat gelatinous, and grey or pink. On pressure a great deal of frothy fluid and a considerable quantity of blood exuded. Excised portions floated in water. This change will be referred to as partial infiltration and oedema. In the right lung the posterior two-thirds of the upper lobe and the postero-superior three-quarters of the lower lobe were swollen, and occupied by red hepatization. Between the hepatization in the lower lobe and the visceral pleura was a zone of lung which showed a few small speckled areas of aeration, but was for the most part airless, smooth, red, and collapsed. The remainder of the right lung showed chronic vesicular emphysema. Occasionally there was a little grey mucus in the frothy fluid which exuded from the bronchioles. The pulmonary arteries in the lower lobe of the left lung at a little distance from the hilum contained red thrombus.

In Case 2 the anterior fifth of the left upper lobe, the right middle lobe, and the anterior quarter of the right upper lobe showed vesicular distension and great interstitial emphysema. The lower fringe of the left lower lobe was partly speckled by aeration, partly collapsed, and congested. The lower quarter of the left lower lobe felt shotty, and on section showed pinhead nodules of peribronchiolitic consolidation in an injected, collapsed ground. The remainder of both lungs was swollen and occupied by partial infiltration and oedema. The scattered granular areas in this partial infiltration measured in diameter about 0.7 cm. in the upper and lower lobes of the left lung, and 1 cm. in the upper lobe of the right lung; in the lower lobe of the right lung was an area of red hepatization 3 cm. in diameter. The frothy fluid which exuded from the bronchioles was everywhere slightly clouded; in the upper lobe of the right lung it contained grey mucus, in the lower lobe of the right lung it contained yellow muco-pus. The mucosa of the bronchi and trachea was covered with blood-stained, slightly purulent mucus. One or two pulmonary arteries in the lower lobe of the left lung contained red thrombus near their terminations.

In Case 4 there was red hepatization in the apex, and in the lower border of the left upper lobe to within 5 cm. of the tip of the lingula; and there was partial infiltration and oedema in the remainder of the posterior two-thirds of the left upper lobe. Red hepatization occupied also the posterior third of the middle lobe of the right lung. Congestion and collapse affected a few lobules in the lingula, and a subpleural zone in the lower part of the posterior border of the lower lobe of each lung. The remainder of the lungs showed chronic vesicular emphysema. Milky mucus came from the bronchioles in the collapsed lobules in the lingula, and grey mucus from some of the bronchioles in the area of hepatization in the right middle lobe, the collapsed area in the left lower lobe, and the aerated portions of both lungs. The mucosa of the bronchi and trachea was covered with frothy mucus flecked with pus.

The largest amount of pleural effusion was an ounce in Case 2. A thin layer of fibrin lay upon the upper lobe of the left lung in Cases 1 and 4, and on the diaphragmatic surface of the left lung and on the outer surface of the upper lobe of the right lung in Case 2. In all three cases there were petechiae in other parts of the visceral pleura.

The changes in the lungs were thus to the naked eye closely similar to those in Group E, Case 1. There was, however, more evidence of broncho-pneumonia, especially in Case 2. Thus, there was an area of collapse, peribronchial consolidation, and muco-purulent bronchitis in the lower part of the lower lobe of the right lung in Case 2, and there were areas of collapse in all three cases. In all lungs many bronchioles contained mucus, and in Cases 2 and 4 some contained muco-pus. In Cases 2 and 4 there was muco-purulent bronchitis and tracheitis. In Group E, Case 1 the microscope showed two distinct changes in the lungs: (1) a peculiar haemorrhagic vesicular pneumonia, complicated by pulmonary thrombosis and free from bacteria; and (2) a muco-purulent bronchitis in which bacteria were numerous and which was occasionally associated with resorption collapse. The naked-eye appearances of the later three cases suggest a combination of similar pneumonia with more advanced broncho-pneumonia.

The bronchial glands were anthracotic and very oedematous; in Case 2 areas that were not anthracotic were engorged and infiltrated.

The spleen in Case 1 weighed 198.5 grams, felt soft, and had a moist cut surface in which the Malpighian bodies and trabeculae appeared swollen and blurred in a pink pulp. In Case 2 it weighed 311.8 grams, felt soft, and had a moist cut surface in which a swollen, deep red, soft pulp obscured the Malpighian bodies and trabeculae. In Case 4 it weighed 262.3 grams, was flabby, and had a cut surface in which an abundant soft, purplish-red pulp obscured the Malpighian bodies and trabeculae.

Muscle.—In Case 2 there were in the right and left *rectus abdominis* irregular areas in which the muscle was somewhat waxy, very pale, and yellowish-pink. They were most numerous in the upper and lower ends of the recti, and the largest area measured 2 by 2 by 0.8 cm. There were thin layers of blood between these areas and the posterior sheath. Near the upper end of the left rectus was a ragged tear, 0.5 cm. long. The other abdominal muscles, the pectoral muscles, and the muscles of the right thigh showed no abnormality. In Case 4 there were haemorrhages into the right and left rectus abdominis: the largest measured 11 by 1 cm. and occupied the lower end of the left rectus and its sheath. There was a group of haemorrhages in an area of 4 cm. diameter in the right and in the left gluteus maximus.

Alimentary Tract.—The stomach in Cases 2 and 4 was congested, and there was in each case an area of slight haemorrhage into the mucosa of the body. There was slight patchy congestion of the small and large intestine in Cases 2 and 4. In Case 1 the mucosa was congested and covered by prune-juice blood, and there were haemorrhages into the valvulae conniventes, in the jejunum for two and a half feet beginning five feet below the duodeno-jejunal flexure. In this case the ascending and transverse colons were distended by gas. The congestion and slight mucosal haemorrhages were probably the result of heart failure. There was no evidence of enteritis. The intestinal lymphoid follicles and the mesenteric glands were not inflamed. The small intestines contained yellow chyme, and the large intestines a little yellow, or olive green (Case 2), semi-fluid faeces.

The brains and cords showed congestion and oedema. There were ring-haemorrhages in the brain and cord of Case 4, and in the cord of Case 2.

We wish to express our indebtedness to Dr. O. Leyton and Dr. D. Hunter of the London Hospital; and to Drs. F. Porter Smith, W. J. C. Fenton, E. Herga, A. Y. Milne, C. W. von Bergen, S. J. Ormond, M. Radford, F. Rushworth, M. R. Mistry, B. Hood, G. C. Pether, J. G. O'Brien, E. W. Masterman, N. H. Linzee, J. L. Boyd, and R. Clark for their valuable co-operation. We also wish to thank Dr. P. N. Panton for the blood counts; Drs. S. P. Bedson and G. T. Western for laboratory investigations, blood cultures, and agglutination tests; Professor H. M. Turnbull for the pathological reports; Colonel A. E. Hamerton of the Zoological Society; and the Ministry of Health.

THE ETIOLOGY OF PELLAGRA.

BY

W. R. AYKROYD, M.D. T.C.D.,

BEIT MEMORIAL RESEARCH FELLOW, LISTER INSTITUTE OF PREVENTIVE MEDICINE.

PROFESSOR WILSON'S note on the etiology of pellagra,[1] published in the *British Medical Journal* early this year, tends to give a wrong impression of some recent researches in connexion with that disease. Wilson's theory of pellagra is that it follows diets in which the biological value of the proteins consumed daily falls below the value of 40 to 45 grams of meat protein, a theory developed as the result of a series of observations made in Egypt during the war.[2] At that time Goldberger and his colleagues of the U.S. Public Health Service had begun the long and eventually satisfactory investigation in the course of which they showed the non-communicability of pellagra, its clear association with faulty diet, and the methods, simple from a scientific point of view, required for its prevention; and their work was already lending fresh point to old theories of the dietary origin of the disease.

Wilson has shown that a number of diets on which pellagra developed contained only proteins of low biological value. The values of the different proteins are taken from Thomas's tables,[3] Thomas having defined biological value as the number of parts of body nitrogen replacable by 100 parts of the nitrogen of the foodstuff. His method consisted in remaining for a few days on a nitrogen-free diet until his nitrogen output fell to a low figure, taken to represent only endogenous metabolism, and then testing the power of various proteins, fed as additions to the nitrogen-free diet, to replace the nitrogen lost in tissue destruction.

Thomas's values, gained from experiments on himself, have not been exactly confirmed, either for man or the lower animals. Martin and Robison[4] have pointed out how difficult it is for those using Thomas's method to avoid fallacies; for example, it is uncertain whether Thomas, previous to conducting his tests, always remained long enough on a nitrogen-free diet for his output of nitrogen to fall to a minimum and represent only endogenous metabolism. These observers attempted with great care to discover in themselves the biological value of the proteins contained in milk and whole wheat. Using Thomas's formula for their calculations, their values for whole wheat (35 per cent. C. J. M. and 31 per cent. R. R.) agree fairly well with that of Thomas (39.50 per cent.), but in the case of milk the difference was very large (51 per cent. C. J. M. and 100 per cent. Thomas). The later workers at first found that with milk nitrogenous equilibrium could not be attained until over 11 grams of milk nitrogen were taken (to replace about 2 grams of body nitrogen), thus giving a very low biological value (about 20 per cent.), but when the energy content of the diet was raised far above normal, nitrogenous equilibrium was attained at a lower level of nitrogen intake. Martin and Robison's paper gives many illustrations of the difficulties underlying determinations of this kind, and their results show the unwisdom of accepting Thomas's figures as absolute. It is remarkable that while he recorded the biological value of milk protein as 100 per cent., he recorded also large negative balances with "Frauenmilch"—cow's milk with extra sugar and cream.

Thomas's results are of interest in connexion with pellagra in that he assigned a low value to maize (29 per cent.), which fits with the earlier observation of Kossel and Kutcher,[5] and Osborne and Harris,[6] that zein, the principal protein of maize, is deficient in lysin and tryptophane respectively. McCollum,[7] using Thomas's method and working with pigs, found that zein could cover 73 per cent. of the animals' nitrogen expenditure. Similar experiments were made on rats by Mitchell,[8] who gave maize a value of 72 per cent., but found it inferior to milk and muscle.

Later, McCollum[9] and his co-workers, taking the growth of rats as index of the biological value of a protein, assigned maize a very low position in the scale relative to beef muscle and wheat. With the pig as the experimental animal Hart and McCollum[10] found the growth value of the proteins of the wheat, maize, and oat kernels roughly equal. These growth experiments are difficult to interpret in that they are complicated by then unrecognized vitamin deficiencies.

It will be seen that it is unwise for the pellagra investigator to place implicit trust in current estimations of biological value. Actually the clinical evidence available at the moment tends to minimize the importance of protein deficiency in pellagra.

In 1920 Voegtlin, Neill, and Hunter[11] showed that remarkable improvement could be produced in pellagrins by the administration of a 95 per cent. alcoholic extract of ox liver in daily doses equal to 1 kilo of fresh liver. The extract was practically free from amino-nitrogen. A few years later a series of observations of a somewhat similar nature led Goldberger[12] to change his earlier view of the causation of pellagra, which coincided with Wilson's. Pellagra being a recurrent disease, it was observed that in certain asylums and institutions in the Southern United States a constant proportion of inmates tended to fall victims year by year, and it was found possible by Goldberger and his associates to study the pellagra preventive effect of alterations in the diets of certain groups.

They discovered that a liberal allowance of casein previously purified by repeated washings in acidulated water (Thomas gives casein the biological value of 70 per cent.) had no effect in preventing the recurrence of the systematic lesions of pellagra, though it had some effect in curing and preventing the characteristic dermatitis. Having at about this time accidentally noted that yeast was effective in treating and averting black-tongue in dogs (I can find no reference in Goldberger's work to the statement, put forward by Wilson, that yeast is operative only in the early stages of black-tongue, while lean meat will cure advanced cases) Goldberger began successfully to use it as a pellagra preventive and in the treatment of developed cases. The yeast used by him was a proprietary preparation—"Yeast Vitamin Harris Powder," which is a dried acidulated watery extract prepared "according to a somewhat modified Osborne-Wakeman technique," and containing very little protein nitrogen.[13]

The success of this yeast preparation (in doses of 15 grams per day) in preventing and treating pellagra led Goldberger to postulate a non-protein P.P. (pellagra preventive) dietary factor in yeast and in other foodstuffs possessing similar preventive properties. These foodstuffs were found to be mostly those containing animal protein, tomato juice being an exception.

Recently Professor Tscherkes, of the Department of Nutritional Research in Russia, has obtained results in the treatment of pellagra, not yet fully recorded, which confirm some of Goldberger's observations. In 1929 a severe outbreak of pellagra occurred in the Ukraine, the drought of 1927 and 1928 having destroyed all crops except maize. A daily allowance of 1.5 litres of milk, 200 grams of meat, or 45 grams of yeast, was found to clear up symptoms in five to six weeks.

Black-tongue in dogs, which owes its name to superficial areas of necrosis on the tongue, appears to have a geographical distribution in the United States similar to that of pellagra, which it resembles in involving a disturbance of the alimentary tract—stomatitis and diarrhoea. It can be produced experimentally in dogs by diets similar to those associated with pellagra in man and cured or prevented by foods containing abundance of the P.P. factor. Doubt has been thrown on the parallelism of experimental black-tongue and pellagra by the production in dogs by Underhill and Mendel[14] of an apparently identical condition which does not respond to treatment with yeast. Underhill and Mendel's syndrome is curable by butter (found useless against pellagra and Goldberger's black-tongue) and by crystallized carotene, which has since been shown to be closely allied to, or a possible precursor of, vitamin A.[15] Since the basal diets used in their experiments were lacking in this vitamin, it is possible that Underhill and Mendel's syndrome had its origin in vitamin A deficiency.

In 1926 Goldberger and Lillie[16] observed failure of growth and a pellagra-like condition in the albino rat when highly purified diets devoid of the P.P. factor were fed. This pellagra-like condition, whose most striking feature is a symmetrical dermatitis, was subsequently produced in other laboratories (Chick and Roscoe,[17] etc.). The external appearances of this condition resemble human pellagra, though the appearance of the lesions does not seem to be accelerated by exposure to strong light. Diarrhoea is not usual in the rat. Findlay[18] has recorded stomatitis. The factor in whose absence rats fail to grow and often develop symmetrical dermatitis is called in this country vitamin B_2 (in the United States vitamin G). It has generally been supposed to be identical with Goldberger's P.P. (pellagra preventive) factor.

Later Aykroyd and Roscoe[19] showed that the distribution of vitamin B_2 (rat factor) was roughly similar to that of Goldberger's P.P. factor and to the black-tongue preventive factor.

Comparison of the Effects of Various Foodstuffs on Vitamin B_2 Deficiency in Rats, on Pellagra in Man, and on Black-tongue in Dogs.

Material.	Rat Vitamin B_2.	Man P.P. factor.	Dog Black-tongue preventive factor.
Maize endosperm	Very poor	Associated with pellagra in U.S.A. and Italy	—
Wheat flour	Very poor	Associated with pellagra in U.S.A.	Used in basal diet to produce the disease.
Whole maize	Poor; 50% less than normal growth	Traditionally associated with pellagra	No preventive action, used in basal diet to produce the disease.
Whole wheat	Poor, but better than maize	—	65% in diet delayed onset of the disease; no protection.
Peas	30-40% needed for good growth ("Clipper" peas)	30-35% (168 gram daily), incomplete protection (Virginian cowpea)	58%; slight protection, 73%; almost complete protection (Virginian cowpea)
Wheat germ	15-30% good growth	30%; protection almost complete	31%; protection almost complete.
Fresh milk	5-10% milk solids, good growth	20% solids (1,200 g. buttermilk daily) protected	250-300 c.cm skim milk daily protected.
Lean meat	7-10% (dry wt.) good growth	13% (dry wt. 50 g. daily) protected	11% (dry weight) protected.
Dried yeast	1-3% good growth	7% (30 g. daily) protected	5% protected.
Liver	1-2% (dry wt.) ox liver, good growth	Alcoholic extract of ox liver effective in treatment	11% dried pork liver protected.
Dried egg yolk	7-15% good growth	—	17% protected.

The results for pellagra and black-tongue are taken from the work of Goldberger, Voegtlin, and others. Estimations of both the P.P. factor and the black-tongue preventive factor are approximate, since in few cases was any attempt made to discover the minimum necessary for protection. The amounts given in all cases are expressed as the percentage of the dry weight of the diet. Goldberger's clinical experiments on pellagra prevention were carried out in institutions under very carefully regulated conditions. Apart from the test foods the diet offered to the potential pellagrins was kept very constant throughout the investigation.

In the series of experiments from which the results in the table are drawn, over 60 per cent. of control rats on a basal diet, free from vitamin B_2 but otherwise complete, developed pellagra-like symptoms. The rat, however, does not develop these symptoms on diets similar to those which are associated with pellagra in man and experimental black-tongue in dogs, and is, indeed, able to perform some growth and remain free from obvious symptoms on such diets. Only a very highly purified food mixture will induce rat "pellagra," and at present the appearance of symptoms is somewhat intermittent. Experiments on rats cannot therefore prove pellagra to be a deficiency disease, but the fact that the rat's needs for vitamin B_2, set, perhaps, on a low scale, are satisfied by various foodstuffs in their order of potency as regards the P.P. (pellagra preventive) factor and the black-tongue preventing factor, is suggestive of the identity of the three factors.

The relatively high vitamin B_2 value of one sample of whole maize employed in our experiments (another sample of maize gave a lower value) is used by Wilson to calculate the vitamin B_2 value of various human diets. Calculation on this basis gives all diets containing much whole maize a fairly high vitamin B_2 value. It is not legitimate, however, to argue, as Wilson does, that because a diet containing 65 per cent. of maize endosperm gives subnormal growth, a diet containing 100 per cent. will produce normal growth. Maize endosperm should be reckoned a negligible source of vitamin B_2.

It is dangerous to put confidence in calculations either of the biological value of the proteins of a human dietary from Thomas's figures, or of its vitamin B_2 value from such observations on rats as now exist. Thomas's values need confirmation, and the distribution of the rat factor is not completely known. Human dietaries are rarely described with exactitude—for example, it may make a considerable difference whether the term "meat" includes offal, or whether it represents sheep, ox, or horse muscle. So far vitamin B_2 has been found most abundantly in foods containing animal protein—that is, eggs, milk, meat, liver, etc.—of high "biological value." Human dietaries are therefore liable to coincide roughly as regards their vitamin B_2 value and the biological value of their proteins. Many diets associated with pellagra, as Wilson says, are low in both respects.

The vitamin (as against the protein) deficiency theory of pellagra rests on the proved possibility of preventing and curing the disease with non-protein substances. The failure of casein to give complete protection against the disease in man and the production in the rat of pellagra-like symptoms on a diet containing this "good" protein, point in the same direction.

It remains to be seen whether the distribution of vitamin B_2 in foodstuffs when known more completely will explain the epidemiology of pellagra in man. Maize was found poor in vitamin B_2 (relative to other foodstuffs), and most pellagra is associated with a high consumption of maize. The equally low vitamin B_2 content of white wheat flour fits in with various observations in the United States of the occurrence of pellagra in districts where wheat was the principal cereal in use. On the other hand, it raises the question why pellagra does not occur elsewhere in ill-nourished populations on a wheat flour staple—for example, in Newfoundland or Labrador, or the East End of London. Complete acceptance of the vitamin hypothesis involves an explanation, in terms of that hypothesis, of the non-occurrence of pellagra in millet-eating countries and its very rare occurrence on rice. Experiments are being carried on to elucidate these points.

While the whole question is still open, the evidence at the moment seems decidedly against the theory of amino-acid deficiency. Investigation of the distribution and properties of vitamin B_2 seems a promising line of attack, though at present it would be premature to regard vitamin B_2 deficiency and pellagra as synonymous.

THE INJECTION TREATMENT OF HYDROCELE.

BY

ST. GEORGE B. DELISLE GRAY, M.D., B.S.,

HONORARY SURGICAL REGISTRAR, HOVE HOSPITAL.

IN 1903 J. C. Luke of Ocilla, Georgia, U.S.A., reported several cures of hydrocele by iodine and carbolic acid injections, and claimed almost uniform success.[1] Nine years later H. Morestin[2] introduced his treatment of vaginal hydrocele by injection of carbolic acid after removing some of the fluid. At first Morestin withdrew about one-third of the fluid and injected 1 c.cm. of a mixture of equal parts of carbolic acid, glycerin, and alcohol. He found that there was no pain, although there was a considerable reaction within the following few days, the scrotum swelling to a considerable size. After a few days all the oedema subsided and the vaginal swelling gradually diminished, and at the end of a few weeks the hydrocele had completely disappeared. As his experience increased Morestin became bolder, and evacuated more of the contents of the hydrocele, until finally[3] he left only a small quantity of fluid in the sac, and injected 1, 2, 3, or even 4 c.cm. of his modifying fluid. In 1912 S. Mallanah described a vaccine treatment for hydrocele in the *British Medical Journal*.[4] The vaccine was injected into the sac.

Soubeyran[5] states that Monod, in treating this condition, injected 1 gram of alcohol 40 per cent. diluted in equal quantity of water without evacuating any fluid. Dimmricher and Polaillon used 1 c.cm. of a 10 per cent. solution of zinc chloride; this also was injected into the sac without withdrawal of fluid. These two procedures were frequently followed by recurrences. Into the sac, previously emptied, all sorts of fluid, from milk to port wine, have been injected.[5]

The satisfactory treatment of a large number of varicose veins by the injection method has induced me, like Pybus,[6] to attempt a modified injection treatment for hydrocele.

Rationale.

A hydrocele is a closed sac lined by endothelium, and containing fluid which has a certain amount of fibrinogen in it. Hydrocele fluid, however, seldom clots, because it is not in relation with damaged tissue. In injecting varicose veins the results are obtained by causing gross surgical injury to the endothelium, which is mesoblastic in origin, and which reverts to its connective tissue type; the vein consequently becomes lined by fibroblasts and damaged endothelium, on which is deposited a very firm thrombus. If the entire endothelium of a hydrocele could be damaged, thus causing an outpouring of fibrin ferment, theoretically the fluid ought to clot and the sac to be obliterated. This was what was aimed at in the old days, when strong iodine was injected into the emptied sac. The trouble in those days was that there was no certainty of destroying the entire endothelium; this was probably because the sac was not distended with the irritant, which therefore did not reach into all the nooks and crannies. In addition, a small amount of hydrocele fluid still remained in the sac; this was probably coagulated, and absorbed a certain amount of the iodine, thus rendering it inert. If the sac were completely distended with irritant for several minutes and then emptied again, the whole of the lining endothelium in every nook and cranny would be destroyed.

I was rather chary of using quinine, because I had come across one or two patients with marked quinine idiosyncrasy, and was afraid that, if the sac were completely distended with quinine urethane solution, in a case of idiosyncrasy too much might be absorbed. I therefore decided to try injecting 25 per cent. sodium chloride into the sac, distending it completely, but with the intention of letting it out after a few minutes so as to avoid any severe caustic effect. The clinical details of two of these cases are as follows.

A patient who had had a hydrocele of about one pint for seven years, and had been tapped many times, was anxious to get rid of it, as it worried him because it was heavy. He was considered a bad operative risk on account of an old injury to his chest, which limited his expansion. I explained what I should like to do as an experiment; he agreed, and in November, 1923, I aspirated his hydrocele through a large needle such as is used for injecting bismuth emulsion, and then filled the sac with 25 per cent. sodium chloride, distending it completely. Great pain followed in the scrotum and testicle, extending to the inner side of the thigh and groin, and passing up into the kidney region. I held the solution in for five to ten minutes to make sure that the whole of the endothelium of the sac was destroyed, and then tried to let it out; it would not come, and I suspected at once that a large slough would develop. A bigger trocar and cannula was tried, but with no result. I attributed the fact that the fluid would not flow out to the retention in the sac of some of the hydrocele fluid; the strong sodium chloride had caused outpouring of the tissue juice from the damaged endothelium so that the diluted hydrocele fluid had clotted, and, although it was not a thick clot, it was firm enough not to flow out through the trocar and cannula. At the end of a week half the scrotum became gangrenous and sloughed off, and he had fungous testis. When the slough separated (including all the tunica vaginalis) the wound granulated over in three or four weeks, and the hydrocele was completely cured. The resultant scar is not nearly so noticeable as one would have expected; he is highly satisfied with the result, as he does not have to carry about an enormous hydrocele.

Another man came to see me about the same time. He had had a hydrocele for some months, and it was getting large, so I took him into hospital. Under a local anaesthetic I made an incision in the skin a quarter of an inch long, and inserted a very large trocar and cannula; I withdrew the trocar, and in its place inserted a soft rubber catheter which fitted the cannula exactly. The fluid was allowed to escape, and the sac was washed out with normal saline. The first washing came away coloured yellow, showing that the sac had not been completely emptied of hydrocele fluid. After two or three washings the sac was distended through the catheter with 25 per cent. sodium chloride with 1 per cent. novocain. The patient felt a little pain, but not nearly so much as the first man; it was similarly referred to the scrotum and testicle, the inner side of the thigh and groin, and extended up to the kidney region. I pinched the catheter and left the fluid in for five or ten minutes, when it flowed out quite easily through the catheter; the tunica was washed out with normal saline solution two or three times, and was emptied as completely as possible. The trocar and cannula were then pulled out, one stitch being inserted into the small incision, and the patient was sent back to bed. He complained of some pain, so was given 1/12 grain of heroin. The next morning he was up and helping in the wards; he had no pain, and was discharged; at the present day it would be impossible to tell on which side he had the hydrocele.

I then read of Morestin's method of treatment, and tried it on three patients about nine months ago. In two cases I evacuated two-thirds of the contents of the sac (about the size of a closed fist) and injected 2 c.cm. of Morestin's fluid. With one patient the result was eminently satisfactory; with the other I was very disappointed. I saw the latter man about a month after the injection, and the hydrocele was larger than it had ever been. He walked into my consulting room about a fortnight ago and asked me to look at his scrotum. The hydrocele had completely disappeared.

In the case of the third patient I evacuated about half the contents and injected about 4 c.cm. of Morestin's fluid. With this patient also I was grievously disappointed at the time, but, after seeing the sequel in the second patient, I went to call on him, and, to my delight, found that his hydrocele was cured.

As modified by Soubeyran, Morestin's technique is as follows.

A hypodermic syringe and small trocar are all the instruments required. It is unnecessary to use local anaesthesia or to shave the scrotum. The place of puncture is painted with tincture of iodine of double strength. The patient is recumbent. The operator makes certain of the position of the testicle, and punctures below and outside if the gland is behind; if it is in front he inserts the trocar from behind.

1. The trocar is sharply plunged into the cavity, and the point can immediately be felt free therein.

2. The hypodermic needle is then inserted a little above the trocar and up to the shoulder of the needle. Its mobility in the sac must be demonstrated by turning it in all directions.

3. The trocar is withdrawn and the hydrocele fluid allowed to flow out slowly and almost entirely. It is a good thing to leave a small quantity in the sac to prevent the action of the carbolic acid from being too caustic.

4. As soon as the cavity is sufficiently evacuated, the trocar is withdrawn and by means of the syringe 2, 3, or 4 c.cm. of Morestin's fluid is injected. It is necessary to make the insertion very slowly, drop by drop, turning the point of the

needle in all directions so as to mix the liquid injected with that in the hydrocele.

5. The hypodermic needle is withdrawn and the scrotum is kneaded, so as to ensure the fluid reaching all parts of the sac. The puncture holes are then dressed with collodion.

No suspensory bandage is necessary, and the patient can get up if he wishes. After the injection he may feel slight pain in the testicular region radiating up the cord, but in a large number of cases there is no pain at all. At the end of a few hours the scrotum swells, becomes heavy and oedematous, and some liquid re-forms, but this is all reabsorbed. Soubeyran claims that at the end of four or five days regression begins, and is complete in two or three weeks.

It is also claimed that this injection of Morestin's fluid is quite safe for use in congenital hydroceles in children, but that iodine in these cases would be very dangerous on account of the risk of penetration into the peritoneum through the open mouth of the sac.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

UNSUSPECTED TRICHINOSIS.

THE following case seems to be worth recording, if only on account of the rarity of this disease in England.

On March 6th one of us (E. H.) was called to see a young woman, aged 27, who complained of having a swollen face; this had come on overnight, and she only remembered having had a cold a few days previously. On examination oedema of the face was noticed, and particularly oedema of the eyelids. On the next day the oedema increased, and was specially intense over the maxillae. The temperature was 99.2° F. As an infection of the antra was suspected, Dr. Vitenson washed out both, with negative results. Examination of the urine, which had a peculiar deep red colour, was also negative. On the following day the temperature rose to 102° F., and the patient complained of pains all over; there was headache and pain on moving the eyes. The exhibition of salicylates gave no relief.

On March 9th the temperature rose to 102.3° F., and the pains increased in severity; moving the patient caused her to scream with pain. Chewing, opening of the mouth, and yawning were extremely painful. The biceps, deltoid, masseter, and temporal muscles were extremely sensitive to the touch; the joints, however, were not affected. The knee-jerks were slightly diminished. On the 10th and 11th the same picture was present, but, in addition, the neck muscles began to hurt, and the abdominal muscles were tender.

A provisional diagnosis of trichinosis was made reluctantly, but the subsequent blood count verified it. On March 12th the count was: polymorphonuclears 43 per cent.; lymphocytes 24 per cent.; mononuclears 9 per cent.; and eosinophils 24 per cent. On the next day the eosinophils had risen to 25 per cent.; there was hoarseness and slight difficulty in deglutition. A specimen of faeces was examined, but nothing abnormal was found. On March 14th and 15th the patient complained of severe pain in the girdle area and hiccup. There was throughout the illness obstinate constipation, with insomnia and depression. Treatment with 5-grain doses of thymol three times daily was started, and during the next few days the illness began to abate. The temperature on the 18th went down to normal: there was slight itching of the soles of the feet and palms of the hands, and severe itching of the nose. On March 21st eosinophils had risen to 40 per cent., and the blood status on March 23rd was as follows: leucocytes 13,000; polymorphonuclears 39 per cent.; lymphocytes 18 per cent.; hyalines 3 per cent.; and eosinophils 40 per cent.

On going into the history of this case we were able to discover that a few weeks previously the patient had eaten a piece of raw bacon on bread, not wanting to make a fire and fry it. That we think was the probable source of infection.

We are recording this case here, although the patient has not quite recovered and our investigations are not completed, because we think it quite possible that other cases of this disease may occur, and are occurring at present in London. It is very likely that they are being mistaken for rheumatism, as trichinosis is practically unknown in this country. It is agreed that this disease almost invariably appears in epidemic form, and we are wondering whether there will be further cases. We also would like to suggest a tightening up of meat inspection, since it is extremely easy to overlook trichinosis if no microscopical examination of the meat is made. It is true that the frying of the bacon makes the trichinae innocuous, but there is need to warn the public against eating raw bacon in any circumstances, since trichinosis is an extremely distressing disease and may assume epidemic character if precautions are not taken.

E. HERZBERG.
London, W.1. I. VITENSON.

Reports of Societies.

COLIFORM INFECTIONS OF THE GENITO-URINARY TRACT.

AT the meeting of the Medical Society of London, on March 24th, with Mr. DONALD ARMOUR in the chair, Sir THOMAS HORDER opened a discussion on coliform infections of the genito-urinary tract, dealing particularly with their clinical aspects.

Sir Thomas Horder remarked that before beginning to study this disease certain associated pathological conditions must be borne in mind or a broad view be taken of the pathogenesis. The mechanism of infection must be considered if the cases were to be dealt with on a right basis. The avenue of infection of the urinary tract was dubious. Although proof was extremely difficult, there was no reason *a priori* against the view that in an acute case the urinary tract had been invaded from the blood stream. Those concerned were generally content, however, to regard the infection as not haematogenous, but entirely local. The evidence of occasional positive blood culture did not take one very far. The lymphatic route was equally difficult to prove, and almost impossible to disprove. The proximity of the colon to the renal pelvis, and perhaps the special tendency of the right kidney to infection, were highly suggestive, but nothing more. An ascending route was postulated when there were urethral or bladder infections of an obvious kind, generally associated with prostatic enlargement, stricture, neoplasm, or calculus; it was possible that this route was followed in some cases, for which the term "primary" was used. It did not follow that because there was no evidence of interaction going on in the bladder the route of invasion of the renal pelvis was not the ascending one. The female urethra was very short, and the disease was more common in women than in men. But the argument at all points was difficult. He had seen what appeared to be a well-marked case of direct infection from wife to husband during the honeymoon, and more than once had seen what seemed to be direct infection from husband to wife. In all these questions it had to be borne in mind that the renal pelvis was by far the most susceptible part of the urinary tract. It did not necessarily follow that when the form of onset suggested a pyelitic origin the organism was not present in other parts of the tract at the same or an earlier period. He had wondered whether in some cases the prostate was the organ or tissue through which the infection reached the tract. Very acute cases occasionally occurred in young adults in which the initial symptoms were urgent dysuria, strangury it might be, and with no clinical suggestion of pyelitis. Quite certainly the prostate was not infrequently the source of reinfection in cases which had for a time been quiescent.

The frequent association of disease in the alimentary tract with urinary infection was universally accepted, and perhaps occasionally overstressed, but that was a less serious error than to overlook it. The alimentary tract might show merely an associated coliform infection, but

that again was difficult to prove. When, as was generally the case, the coliform organism obtained from the urine was not, as judged by standard bacteriological features, pathogenic, it was extremely difficult or impossible to say to what extent, if at all, the intestine was also in a condition of sub-infection. Unfortunately, clinicians suffered from the lack of standardization in bacteriological work upon the faeces; there appeared to be some criteria of pathogenicity quite commonly used which the more academic bacteriologist did not attempt. Until there was some standardization in the methods of bacteriological examination of the stools it would be necessary to wait before the question could be settled as to whether or not there was an associated colonic infection. For the present the cruder and no doubt more fallacious tests must be employed, such as the character of the stools judged by the naked eye, and the patient's symptoms, such as flatulence and abdominal pain. The existence of any organic lesion in the alimentary tract might, if unrecognized, result in a urinary infection drifting on for an indefinite time. Extraordinary instances were known where the adjustment of some mechanical disability, connected perhaps with the appendix, effected a remarkable change. Constipation or colonic stasis must be borne in mind as a factor. It was such a common trouble that by the law of averages many patients suffering from coliform infection of the urinary tract must be constipated, but it did not follow that the treatment of the constipation by drastic methods would help them. Some definite cases of urinary infection arose after a few days of looseness of the bowels or actual diarrhoea; these were instances of bowel infection eventually complicated by urinary infection. The adjustment of minor disabilities connected with the alimentary tract, such as piles, contributed to the relief of these cases. He had seen the radical treatment of anal fissure followed promptly by a greater improvement in the urinary infection than he had been able to get by routine treatment.

In diagnosis there were not many points at issue. Familiarity with the disease and realization of its frequency and subtlety abolished surprise at its vagaries. It occurred at all ages, even in infants at the breast, ranging in degree of intensity from an unexplained pyrexia to strangury. Haematuria might be its one striking expression, and some complication, like epididymitis, rather than the main infection, might bring the patient under observation. The disease might masquerade as recurrent influenza. It was not sound to conclude that when the urine was full of bacilli inflammation was not present; how was it that in some of these instances of bacilluria pyrexia might be quite marked? It was rather a quibble whether or not in these cases of bacilluria there was or was not a true inflammatory reaction. What he visualized in this disease was every transition in intensity between a mere bacillary invasion of the tract and the most severe form of infection leading, as it might, to pyelonephritis. It was important, in considering treatment, to enlarge the diagnosis in the individual case as fully as possible, not merely with a view to ascertaining the symptoms and signs of the infection, but the patient's "constitution," his habit of body and mind, and daily routine. At what time in the treatment of the case should an investigation more complete than the ordinary clinical examination be made? Some made the instrumental investigation straight away, but this might be a disservice to the patient. If a full clinical examination seemed to exculpate the kidneys from gross lesion, and there was nothing to suggest vesicular or prostatic disease, and radioscopic examination was negative, he was satisfied to proceed on certain lines until faced with failure of adequate response to the general scheme of treatment.

The planning of a definite scheme of treatment must take account of the patient's habits—questions of exposure, prolonged effort, inadequate rest, irregularity of meals; he had an impression that the disease was quite common amongst doctors. He did not think it was of service to introduce strong purges; rather should one consider what had been the patient's habit in this respect, and proceed slowly rather than drastically. How to change the intestinal flora, and the results if and when this was done, were questions no one was able to answer—except the agencies which advertised various panaceas for the purpose. For some years he had held that diet was an important factor in treatment of some of these cases. He reduced the protein content considerably, allowing butcher's meat not more than three times a week, and rigidly excluding eggs, and especially raw milk. He confessed that at present this part of the regime was only empirical, but he felt sure that the results had been good. It was difficult to get mothers to believe that a child suffering from this disease could exist without milk, and the initial loss of weight following the prohibition seemed to confirm their fears. It seemed to be a matter of the casein residue very largely, because whey, buttermilk, cream, and even junket did not appear to have the deleterious effect of milk. Two remedies seemed to stand out prominently—namely, simple alkalis in the acute febrile stages, and the hexamine group in the subacute and chronic stages. Vaccine treatment should be given a thorough trial in any case which after the first two or three weeks did not respond to these general measures together with urinary antiseptics. Finally there was the question whether a direct attack should be made on the mucous membrane of the urinary tract by chemical agents designed to kill the organism, in the hope that they would prove harmless to the tissues. Bladder lavage for purely local infection was of service, but irrigation of the pelvis of the kidney was less to be recommended. Surgery of the more drastic kind—operations on the kidney—had, he supposed, been quite abandoned since the nature of these cases was realized.

MR. KENNETH WALKER said that the ascending route of infection had been amply demonstrated, though some arguments used in favour of it were obviously fallacious; for example, frequency of micturition might be as much a symptom of infected pelvis as of infected bladder. The argument which had been used in favour of lymphatic, as against vascular infection, had been the negative results obtained from blood cultures. Some had tried to get over that difficulty by suggesting that infection by the blood stream was an intermittent phenomenon, but he did not think this could explain the almost consistently negative cultures. It had to be remembered that the coliform bacillus probably did not exist free in the plasma, but rather within the polymorphonuclears, and recent research had shown that if methods were employed for concentrating the leucocytes, positive blood cultures were, generally speaking, more likely to be obtained. In the breaking down of polymorphonuclears also bacteriolysins were very likely to be liberated which destroyed the organism and defeated efforts to cultivate it. There was no doubt that the gastro-intestinal tract was the usual source of infection. That the bowel was a source of infection was proved by the additional fact that if the urine were cultivated anaerobically in a very large number of cases, in addition to *B. coli*, the *Streptococcus faecalis* was obtained. But another fact was still more significant—namely, that if cascara was given to a patient presumably recovered from a urinary infection, *B. coli* immediately returned to the urine; cascara had even been used by Dr. Embleton as a provocative test of cure. As for predisposing causes, the mere arrival of the bacillus in large quantities in the kidney was not sufficient so to act; time after time it had been shown experimentally that large numbers of *B. coli* might be taken into the blood stream without the kidney developing pyelitis or pyelonephritis. Although there were such gaps in the knowledge of the pathology of this condition, fortunately the morbid anatomy was better established. Mr. Walker concluded by saying that there was far too much armchair speculation about *B. coli* infections, and a great deal of work had still to be done to fill in gaps in knowledge.

MR. H. PHILBRICK NELSON reported some experiments on rabbits with a view to ascertaining the route of infection. Out of fourteen rabbits infected, five showed the occurrence of what corresponded exactly to the ascending type. It was through the urethral mucosa and not through the bladder that the organisms entered the lymphatics. He exhibited a number of slides bearing out the results of his

experiments. Mr. J. P. LOCKHART-MUMMERY said that in a number of cases he had tried to discover any source of infection in the large intestine. Piles were very common, but he did not believe that there could be an infection from the large bowel without some breach of surface, and in most cases in which definite lesions had been found these had been fistulae. Another outstanding source of coliform infection was diverticulitis; he did not think he had ever seen a case of diverticulitis which was not accompanied by quite marked coliform infection of the urinary tract. With regard to the method by which the infection occurred, whether by the lymphatics, the blood stream, or direct ascent, he thought that all three methods existed. Dr. T. JOEKES said that treatment by the bacteriophage of d'Herelle had given very good results in some cases, though it had failed in others. It had been possible to isolate very virulent and potent bacteriophage, and he had seen, after twenty-four or forty-eight hours' interval following upon subcutaneous injection, a number of cases in which infections of long standing had cleared up. Injections must not be given too often, because in that event there might be produced an antibacteriophage. The bacteriophage would not work in an acid medium.

Sir THOMAS HORDER, in reply, said that the bacteriophage method, although based upon work done originally by Dr. Twort in this country, had become commercialized in France, so that English visitors in the Riviera who had any of these infections were immediately seized upon and subjected to treatment by this latest method of bacteriophage therapy. He was very pleased to learn that one British pathologist had ventured into this field. Another method of antigen therapy was that introduced by Besredka in the treatment of sub-infections of the alimentary tract—namely, application of the antigen directly to the tissue most susceptible—in the case of the alimentary tract to the mucous membrane of the intestine. Thus in France again the oral method of applying this vaccine therapy had become, for certain diseases, quite fashionable. He wondered whether anyone had been sufficiently adventurous to employ the coliform antigen directly either in the bladder or other parts of the urinary tract. If all that the French claimed for Besredka's method—or even only a portion of it—was true, it might be worth exploring.

SYPHILITIC AORTITIS.

AT a meeting of the Section of Medicine of the Royal Society of Medicine, on March 25th, with the president, Dr. R. A. YOUNG, in the chair, and at which Lord Dawson of Penn, president of the Society, was also present, a discussion on syphilitic aortitis was opened by Dr. ERICH LESCHKE of Berlin.

Dr. Leschke began by urging the need for revision in treatment of the condition. It had often been stated that salvarsan increased vascular syphilis, but this was not true. In Berlin the number of cases of syphilitic aortitis found at post-mortem examination had increased more than threefold during the past few years, but this increase had begun before salvarsan came into general use. At least 18 per cent. of his own cases had never received salvarsan treatment at all. Aortitis was much commoner in men than in women; it might give rise to diffuse dilatation and aneurysm, to aortic regurgitation, or to coronary stenosis. Regurgitation occurred in nearly two-thirds of his cases, and in some cases, as was to be expected, the syphilitic lesion was grafted on a lesion from another cause. Coronary stenosis with angina pectoris occurred in 15 per cent. of his cases, and was often associated with myocarditis. Early diagnosis of aneurysm could only be made by using radiography and the Wassermann reaction as a routine: even so, aneurysms of the concavity of the arch often escaped diagnosis. Treatment should be specific at every stage, without reference to heart failure; salvarsan, iodides, and bismuth could be used. The patient should have a course of twelve injections of neosalvarsan annually. The danger lay in shortening the treatment; intermittent treatment of one injection monthly could be given for years. He had found that the symptoms improved and the condition became stationary under treatment; difficulty in breathing was often relieved, and the pain of angina lessened. He had many cases which were doing well fifty years after infection.

Dr. J. COWAN suggested that the increase in the incidence of syphilitic aortitis might be more apparent than real; accurate diagnosis of the condition was of recent origin, and might account for the increase. It was difficult to treat these cases early because so often the aorta was grossly affected before advice was sought. He raised the question whether intensive treatment was permissible for patients suffering from severe cardio-vascular disease. Intensive measures were valuable for the healthy adult with a primary lesion, but in cases with marked cardio-vascular degeneration milder treatment given over a long period might give better results. Any line of treatment which led to deterioration of the general health was harmful to the patient. In conclusion, he would emphasize the importance of rest for these cases, especially during treatment.

Dr. J. PARKINSON said that diffuse dilatation of the aorta was often due to atheroma alone. The age incidence of syphilitic aortitis was in middle life, but it was impossible to find a patient too old to have aortic dilatation or incompetence due to syphilis. Early diagnosis of aneurysm could be made by radiography. He showed some interesting slides which illustrated the gradual development of aneurysm in the ascending and descending aorta, and the arch.

Dr. T. F. COTTON said that the incidence of late tertiary cases bore a close relation to untreated primary cases. It was hard to assert that cardio-vascular syphilis was on the decline; primary conditions were being more thoroughly treated at the present time, but the results were not yet being found among the late cases. He had taken fifty-five patients who had never received salvarsan treatment, and had given them a course of novarsenobillon once a year for five years; over the same period they had received mercury by mouth or as inunctions. A group of fifty-five control cases had not been given novarsenobillon; there had been no striking difference in the symptoms or signs of the two groups. At the end of five years a quarter of the treated and a third of the untreated cases were dead. At the end of ten years from the beginning of treatment the following table gave his results:

	Treated.	Untreated.
Living	21 (38%)	6 (8%)
Dead	18 (32%)	52 (67%)
Missing...	16 (30%)	19 (25%)
Total	55	77

These figures suggested that the prognosis was not so hopeless as hitherto supposed, and that treatment arrested progressive changes and prolonged life.

Dr. E. STOLKIND agreed that salvarsan had nothing to do with the increased incidence of aortic syphilis, but that improved diagnosis had made an apparent increase. He urged that syphilis of the central nervous system should never be treated by malarial infection if the patient's heart was also affected. Similarly, lumbar puncture should be avoided if possible, especially in cases of aneurysm. He remarked on the fact that syphilis of the cardio-vascular system did not cause fever. He had found digitalis and strophanthin valuable in combination with specific treatment.

Dr. D. E. BEDFORD said that it was important to diagnose syphilitic aortitis early, before aortic incompetence developed; the fact that only one-quarter of Professor Leschke's cases had incompetence showed how excellent must have been his diagnosis.

Dr. T. J. HOSKIN said that he had seen two deaths following intensive arsenical treatment. He pointed out that if all the missing cases in Dr. Cotton's series were dead the conclusions would be considerably altered, but that it was probably fairer to accept half as living.

Dr. A. P. CAWADIAS asked whether it was certain that the increase of these cases was not attributable to the use of salvarsan. Most of those he had seen had received vigorous salvarsan treatment in the past. Bismuth was extremely helpful; its action was slower than that of

arsenic, but it stimulated the immunity processes of the body.

The CHAIRMAN asked whether the transition from aortitis to aortic regurgitation was slow or sudden. In a few cases which he had had opportunity to observe it had seemed to be somewhat sudden.

Professor LESCHKE, in replying, said that the increase in incidence of the condition was real rather than apparent, as post-mortem examinations showed. "Intensive" treatment implied not that any individual dose was large, but that thorough treatment was continued over a long period. Rest was certainly most important for these patients, and should be enjoyed, if possible, in the open air. Malarial treatment should only be used where the myocardium was in good condition; he did not approve of it where aortitis was present. The incidence of syphilitic heart conditions was probably higher in Germany owing to the small proportion of rheumatic cases found there. He had seen no deaths from salvarsan; injections should be made slowly, drop by drop. Regurgitation could certainly arise quite suddenly; in other cases the transition was rather slow. Bismuth was useful with salvarsan, and better results were obtained with intravenous iodine in addition.

EXPERIENCES IN INTRACRANIAL SURGERY.

AT a clinical meeting of the Cardiff Medical Society, held at the Royal Infirmary, on March 11th, with the president, Dr. OWEN LL. RHYS, in the chair, Mr. LAMBERT ROGERS of the surgical unit of the Infirmary described some recent experiences in intracranial surgery.

Mr. Lambert Rogers first reported a case of middle meningeal haemorrhage with atypical clinical features, which had occurred in a farmer, aged 35, who was admitted to hospital in a very restless condition of semi-consciousness, following a blow on the head. Intracranial tension was kept reduced by four-hourly rectal injections of 30 per cent. magnesium sulphate. There was no lucid interval followed by coma, but three days after admission right monoplegia developed and soon progressed to hemiplegia. The systolic blood pressure was only 90 mm. Hg. An osteoplastic flap was turned down over the left motor area, and 82 grams of extradural clot was removed. It was found that a linear fracture of the parietal and squamous bones had torn the anterior branches of the meningeal vessels. The bone flap was replaced and the patient made a complete recovery. Mr. Rogers commented upon the comparative rarity of middle meningeal haemorrhages presenting the textbook clinical picture, and suggested that the atypical features in this case might have been due to brain shrinkage because of the rectal injections. He showed another case following injury; a boy, aged 3, received a blow in the suboccipital region, resulting in fracture. An abscess the size of a small orange developed in the right occipital lobe, but the child completely recovered after the evacuation of 20 c.cm. of staphylococcal pus. Mr. Rogers commented on the desirability of treating surgically in the first place all compound fractures of the skull. Another boy, aged 12, exhibited the signs and symptoms of a right cerebellar lesion, but although the first stage of a suboccipital exploration was performed, tapping of the posterior horn of the right lateral ventricle only gave vent to a few drops of a dark fluid, which contained protein but no cells. Subsequent ventricular estimation had shown the presence of internal hydrocephalus affecting the left ventricle and causing collapse of the posterior horn on the right side. Stereoscopic radiography had indicated an opacity due to a growth in the neighbourhood of the tentorium, which it was proposed to examine through the osteoplastic flap in the occipital region. Mr. Rogers also discussed a case of chronic subarachnoid haematocele, with left abducens palsy and failing vision in a miner, aged 23. The duration of symptoms had been only four weeks, but four dioptres of papilloedema were present, and the vision was reduced to counting fingers at a short distance from the eyes. A brain tumour was suspected, but when, under local anaesthesia, the left frontal and temporal regions had been explored and the left lateral ventricle tapped to reduce tension, only an encapsulated mass of yellow blood clot was removed. Complete recovery followed. Three months before the operation the miner had received a blow over the occipital region.

Other Clinical Cases.

Professor A. W. SHEEN showed a case illustrating the value of splenectomy for purpura. A woman, aged 22, who had shown the usual symptoms and signs, including profuse ten-day menstrual periods, had been treated by dilatation and curetting, the introduction of radium into the uterus, ultra-violet rays, and prolonged administration of iron and other drugs. Her anaemia decreased, but otherwise her condition remained unaffected. After splenectomy remarkable improvement followed; her periods became normal, her colour returned, and she was able to resume her occupation. The tendency to haemorrhage had entirely disappeared, and the platelet count was nearly normal. Other cases presented by Professor Sheen were multiple osteomata in a man, aged 49, and his son, aged 16, and a case of extensive rodent ulcer of the forehead and scalp in a man, aged 54; this had been treated by *x* rays and diathermy, and subsequently by removal of the ulcer, followed by the covering of the denuded area by a pedicled scalp flap.

Mr. ROBERT COOKE showed a case of perineal fistula, which had existed for nearly forty years in a man, aged 60, as a sequel to gonorrhoeal stricture. After much previous treatment had failed, suprapubic opening and prolonged bladder irrigation had been followed by excision of the fistulous tract and its associated length of strictured urethra. Four months later the fistula had closed, the largest sound passed with ease, and all the symptoms had disappeared. Mr. Cooke remarked that excision was not often necessary for gonorrhoeal stricture, but this case illustrated the value of the mode of treatment described when dilatation and urethrotomy had failed. He also showed a case of a boy, aged 14, with double tuberculous epididymitis, tuberculous urethral stricture, and periurethral abscess, in which the bacillus had been identified. He commented on the rarity of this form of stricture, and added that the abscess had healed after being opened and the stricture had been dilated.

SAFE ADMINISTRATION OF ANAESTHETICS.

ON March 24th, before the Royal Scottish Society of Arts, Mr. WILLIAM FULDE of the Heriot-Watt College, Edinburgh, described an apparatus which had taken several years to perfect, and which, in the course of its evolution, had been tested by anaesthetists under hospital conditions from time to time. It was said to enable anaesthetics of different character to be administered under conditions making for complete safety in control. Mr. Fulde showed that he was able, by means of a compact and robustly constructed device, to supply to a patient ether (intertracheal or by vapour mask), nitrous oxide and oxygen, or ethylene (or other gaseous anaesthetic) with carbon dioxide. A single control enabled the ether percentage to be regulated within wide limits, and allowed any required mixture of chloroform and ether to be obtained. A wide range of volumetric supply necessitated by modern requirements had been studied by the designer, who had rendered it possible to supply between 5 and 40 litres a minute, the quantity of mixture actually passing to the patient at any moment being automatically indicated by a simple flow-gauge. The base of the apparatus is a hot-water chamber introduced to heat the air current both before and after that current had taken up the anaesthetic. The water in the hot-water chamber might, in the event of a lengthy operation, be kept at the desired temperature by means of a low-power morganite electric heating element, which could be placed under the chamber. The air current was supplied in any convenient way, as, for example, by a small motor blower, a foot bellows, or from a compressed-air cylinder. Despite the wide volumetric range, care had been taken that the supply to the patient was delivered at a uniform rate. In this way the risk of a pulsating delivery was obviated, and there was complete immunity from the even more serious danger of liquid anaesthetic being carried across. In contrast with older types, this new form was very compact, the whole of it being carried in an averaged-sized attaché-case.

Reviews.

BIOCHEMISTRY.

BIOCHEMISTRY has grown up under the benevolent patronage of medicine. The chief preoccupation of its teachers has been the training of medical students. The majority of biochemical textbooks have, accordingly, been designed to serve medical curricula, and it may be asserted that there are many more textbooks of biochemistry than are necessary to the healthy progress of medical teaching. Particularly is this the case in respect of practical laboratory manuals. In spite, however, of our reluctance to welcome another such, *A Course in Practical Biochemistry*,[1] by Professors CAMERON and WHITE, cannot be passed over without a word of praise. This book seems to us one of the most satisfactory laboratory courses which have yet been published. It covers the usual ground of digestion, blood, and urine, but does so in an attractive and efficient manner which should commend it to many. It forms a valuable laboratory companion to the theoretical *Textbook of Biochemistry* recently published by the senior author.

In Professor R. A. GORTNER'S *Outlines of Biochemistry*[2] we have a book of a different and more ambitious character. Biochemistry has been growing up to ideas of independence. It has been feeling strongly that it is more than a branch of pathology or of applied chemistry. It has a faith of its own—that vital phenomena are open to description in the language of chemistry and of physical chemistry. It has a technique of its own for the pursuit of this faith. Incidentally it has a mission—to urge upon the biologist the value of chemical theory and practice, and upon the chemist the peculiar requirements of the biological point of view. This it believes it can accomplish best from a position of independence. If this is biochemistry then we may say that, at last, we have a textbook of biochemistry. The need has been urgent. Professor Gortner's book presents, as no other single book has done, a measure of the contribution of organic and of physical chemistry to the problems of vital processes. He makes no attempt to distinguish between plant and animal, far less between man and other species. It is the book of biological chemistry. In saying this, we do not overlook a certain lack of balance in the book. The amount of space devoted to the problem of colloidal behaviour seems to be out of proportion to the contribution which present theories of the colloidal state have made, or are likely to make, to the understanding of vital phenomena and their control. It would, however, be surprising if a book did not reflect the special interest of its author, and the discussion of the colloidal state is so admirable in itself that we are inclined to forgive its encroachment upon space which might otherwise have been given to other subjects. The general biological outlook of the book has permitted the assembly of a great deal of valuable material not elsewhere collected in one place. The author exercises wise discretion in the presentation of theories and in the balancing of conflicting views. The text is liberally annotated with references to the original literature. This book may be strongly recommended to students in all branches of pure or applied biochemistry.

LOCAL ANAESTHESIA.

DR. R. E. FARR in his book *Practical Local Anæsthesia and its Surgical Technic*,[3] covers a field far wider than the title of the volume would suggest, for besides giving the technique of local anaesthesia he devotes much space to descriptions of surgical instruments, operating tables, and the lighting of the theatre, and even to the technique of operations—all matters which would more appropriately be included in a work on operative surgery. He is an enthusiast, and therefore inclined when advocating direct infiltration anaesthesia to overlook the advantages of other methods. Thus he seems to have practically no use for general anaesthesia, except in those rare cases where from faulty technique in the application of local anaesthetic methods the operation could not be completed without the help of some general anaesthetic. Nor is he impressed with regional anaesthesia—though he confesses that it is the ideal. The technique of regional anaesthesia is difficult and many punctures are required; the time taken in preparing the patient for operation is therefore prolonged unduly; moreover, heavy preliminary narcotization to ensure comparative insensibility is very necessary, and in many cases supplementary general anaesthesia is required. Intraspinal anaesthesia falls under the general ban, though sacral anaesthesia escapes.

Dr. Farr advocates direct infiltration as being quicker in application than other methods and more under the control of the surgeon. He regards heavy preliminary narcotization with morphine, hyoscine, scopolamine, etc., as being dangerous, though he allows small doses of morphine or heroin to quieten the nervous system and so lighten the ordeal of the patient. The anaesthetic he prefers is novocain in moderate strength (0.25 to 1 per cent.) combined with adrenaline (2 to 5 drops of 1 in 1,000 solution to each c.cm. of novocain solution used). In his opinion the surgeon should himself direct the anaesthesia, but he approves the employment of an individual he calls a "psycho-anaesthetist"—a sort of surgical Pooh-Bah, whose duties include, among others, soothing the patient, superintending the transportation of the patient to and from the theatre, recording the blood pressure, pulse, and respiration, and instructing the patient in the avoidance of straining, grunting, and coughing during the operation. In addition, this individual should be well trained in the administration of general anaesthesia (should this be required), and should help in adjusting the operating table to meet the requirements of the patient and the surgeon.

The author's descriptions are well given, and, on the whole, the volume is satisfactory, even if we cannot agree with everything he says. The publisher has done his work well, and the illustrations are excellent.

DIET, NUTRITION, AND EFFICIENCY.

THE experiments described by Mr. H. H. G. HOLCK in *Diet and Efficiency*[4] represent not only a most laborious and painstaking piece of work, but also a very considerable feat of endurance. He set himself the problem of determining, by objective tests, whether the general dietetic principles of Fletcher did, or did not, make for increased health and well-being. He adopted four dietary measures: (1) eat only when actually hungry; (2) stop when satisfied; (3) chew especially well; (4) as far as possible, try to secure foods for which there is a craving, and omit those to which there is an antagonism. The whole experiment, including the necessary control periods, lasted from 1922 to 1928. The objective tests adopted entailed the following observations: (1) food and water intake, and eating time; (2) number of defaecations; (3) sleeping hours; (4) estimations of total phenols, uric acid, total nitrogen, phosphorus, inorganic sulphates, and acidity of urine; (5) blood pressure, pulse rate, and temperature; (6) ergograph tests; (7) typewriting, arithmetical, and chess problem tests. There is no doubt that thorough and long-continued records of data of this type are very useful from many points of view. With regard to the immediate object of the experiment—the testing of the value or otherwise of "Fletcherization"—all that can be said is that the regime, in this instance, appeared to be productive of no good, while, since ergograph tests indicated a fall of muscular efficiency, it may have done a little harm. This is the impression gathered from reading the text: we could wish that the writer had expressed his own conclusions in a more definite manner.

Dr. ROSEWARNE'S book, *The Science of Nutrition Simplified*,[1] is an excellent one of its kind. So much discussion of dietetics, on such very unsound lines, is put before the public, both by the newspaper press and by individuals, that any sensible survey of the subject is welcome, which, while being comprehensible to the layman, is yet confined in its scope to established scientific fact. It is unfortunate that food lends itself so readily to commercial exploitation, for it is undoubtedly the influence of the patent food manufacturers that keeps dietetics in a wrong focus constantly before the eyes of the public. Only when most people have a sound elementary knowledge of nutrition will food fads cease to flourish; to such books as this we can look to provide the necessary public education.

MINOR SURGERY.

DR. FREDERICK CHRISTOPHER, the author of *Minor Surgery*,[2] suggests that there cannot be too much instruction on this subject, for its scope is wide, its practice cannot be confined to specialists, and its skilled application demands of the practitioner a general knowledge of surgical diagnosis and the ability to differentiate the major from the minor surgical conditions. Professor A. B. KANAVEL, who contributes an introduction, makes the further point that only too often carelessness and incompetence turn minor into major surgery. In the course of his hospital work the student has little chance of acquiring a sense of proportion; he spends so much of his time watching the major surgical procedures that almost inevitably he overlooks the fact that the surgical practice of most practitioners lies in the treatment of abscesses, fractures, and so forth, and in the performance of such operations as circumcision and the removal of sebaceous cysts. In *Minor Surgery* are included the conditions that may be met in everyday surgical practice; Dr. Christopher presents a clear exposition of the injuries, infections, and deformities of different regions of the body, and gives useful and precise directions for their relief and cure. The final chapter is in effect a homily, addressed to the resident house-officer, on how to deport himself, especially in his relations with patients, the nursing staff, and his chiefs. Dr. Christopher has produced a book which should prove useful alike to the house-surgeon and to the private practitioner.

NOTES ON BOOKS.

THOSE who tackle the problem of the after-care and employment of the consumptive will read with sympathy and interest the story of the varying fortunes of the Spero Firewood Factory as told by Dr. BARDSWELL in his *Work Centres for the Tuberculous*.[3] Though not a vast undertaking, this factory is a definite, and in some respects a successful, attempt to find a solution of the problem. A piece of sociological research such as this, involving a capital expenditure of less than £5,000, whose results are judged by stern realities, and which has been conceived and carried out on clear common-sense lines unobscured by a haze of sentimentality and press publicity, is a most valuable endeavour. It is from work of this sort that the solution, if there is one, will come. *The T.B. Patient's Guide*,[4] an excellent little book, whose title explains its object, may with advantage be mentioned in the same company. Dr. BLACKMORE has not worked as the tuberculosis officer for Woolwich for so long without realizing the doubts and difficulties of his patients. His answers to them are kindly and wise.

The *Textbook of Zoology*,[5] by H. G. WELLS and A. M. DAVIES, rewritten by J. T. CUNNINGHAM, has again been extensively revised for the seventh edition by Mr. LEIGH-SHARPE, who has contributed chapters on the cockroach and on the modes of animal life. This edition contains some new diagrams, and the type has been reset.

The edition of *The South and East African Year Book and Guide*[10] for 1930 includes a bibliography of recent books relating to these territories. As already noted, the various sections contain much information, which has been brought up to date. There are 64 pages of maps in colour.

The fifty-fourth volume of the *Transactions of the American Gynecological Society*[11] contains the papers and discussions of the scientific sessions of the fifty-fourth annual meeting of the society, held in May, 1929. The text is illustrated by reproductions from photographs.

The issue of the *Medical Register* for 1930 reveals that 1,410 names were added last year. New registrations numbered 731 in England, 389 in Scotland, 133 in Ireland, and 157 in the colonies and abroad. This total is 246 less than the corresponding figure for 1928. Membership of the medical profession was 54,870 at the end of 1929, an increase of 534. The number of names removed from the *Register* during the year was 920, compared with 1,038 the previous year. Of these 851 were removed on evidence of death, 64 for failure to comply with the inquiries of the registrar as to cessation of practice or change of address, and 5 were struck off under the disciplinary powers conferred by the Medical Act.

The number of dentists appearing upon the *Dentists Register* for 1930 is 14,381, of whom 6,825, or 47.46 per cent., are registered with medical, surgical, or dental qualifications. This compares with 6,824, or 47.43 per cent., so registered in the previous year out of a total of 14,383. Of the 273 British registrations that were added to the *Register* during 1929, 248 were registered with qualifications, and 25 under the Dentists Act of 1921, increases of 9 and 3 respectively. The number restored under the Acts of 1878 and 1921 was 292, and the number removed under these Acts and on account of death was 573. As formerly the *Register* contains a local address list.

The *Medical and Dental Students Register*, issued by the General Medical Council, shows that the number of medical students registered in 1929 was 1,502, which is 140 more than in the previous year. Scottish registrations numbered 626, an increase of 49; English registrations 630, an increase of 86; and there were 246 Irish registrations, 5 more than in 1928. Dental students, registered in 1929, numbered 293, an increase of 42 on the previous year.

PREPARATIONS AND APPLIANCES.

MR. FREDERICK ROQUES, M.Ch., F.R.C.S. (London, W.1), writes: The well-known ligature holder which was designed by Mr. Victor Bonney to be worn on a rubber wristlet possesses two disadvantages, which are probably apparent to all those who use this ingenious instrument. When it becomes old the caps are liable to fall off, whereas when new there is often difficulty in removing them, especially with the gloved hand, and more especially if the gloves are wet.

At my suggestion, Mr. W. Biffen, instrument curator at the Middlesex Hospital, has made for me an improved model of the ligature holder. Each cap of the new model possesses a milled edge with an upright pin which fits into a slot on the barrel of the ligature holder. The slot is grooved twice at right angles. The pins on the new model are longer than those on the old model. The cap slides inside the barrel, thus making slots and pins always visible. Both the former disadvantages are overcome, for the milled edge makes the cap easy to remove, while the long upright pin and the two-way groove make the cap secure.

I have been using the improved model for some months. It is in every way satisfactory, overcoming the disadvantages of the original model, which, if trifling, are at times trying to the patience. The knife at the back of the original barrel, which is really functionless, I have had removed. The appliance can be obtained from the Medical Supply Association, Gray's Inn Road, W.C.1.

British Medical Journal.

SATURDAY, APRIL 5TH, 1930.

SCHOOL ATHLETICS.

THE discussion at the Hunterian Society of London, on March 24th, at which school medical officers and others gave their experiences of the effects of athleticism on growing boys, must have shaken a little the faith of those members of the audience who had hitherto embraced school games as a vital part of their social creed. Dr. Lempriere, medical officer of Haileybury, who opened the discussion, was able to boast that death was a rare result of school athletics, and even then was usually accidental. There were possible abuses of the system; a boy might indulge intemperately in sport, with resulting lassitude, loss of weight, and deterioration of work. Ill effects from exercise, as a general rule, followed some slight disability such as a cold, chill, or influenza. But he was able to make the triumphant assertion that if games and sports were well managed they did little damage. Dr. Simey, medical officer of Rugby, was not able to endorse this view; he said that the competition at present encouraged as part of the athletic system in our schools put a nervous strain on the boys and added materially to the difficulties of the doctor. He reminded his hearers that the word athlete was derived from the Greek ἆθλος, meaning a "contest," and the corresponding adjective, besides meaning "struggling," could be used for "wretched" and "miserable" in a moral sense. This atmosphere of struggle did much to vitiate the good effect of school games; they were played for their own sake, with undue attention to style, instead of for the sake of the body and mind. As a result, boys with artistic tendencies had no opportunity to develop their tastes, and boys with an aptitude for sport became stale. He agreed with Dr. Lempriere about the desirability of introducing a "non-compulsory changing" day in the school week. Dr. Helen Boyle doubted whether the cult of athleticism was producing better citizens. She emphasized the difference between succeeding generations, and the need for continual reconstruction of education to suit new needs. Games should teach something, if only how to be a fool without looking one; at present they certainly served a purpose in preparing children for the conflicts of later life.

There can be no doubt that the existing system does interfere with the development of many children who are out of the ordinary. A child may be extremely energetic, and yet detest organized games, and much may be urged against taking such a child from an imaginative game of his own invention, in which he is exercising both body and mind, in order to compel him to join in a sport which he loathes. There is a danger that he will retaliate by a sullen boredom and avoidance of exertion, which robs the exercise of its whole value. We are far from suggesting that the introverted child should be encouraged in his flight from reality; but it is at least open to question whether compulsion is the most desirable or only method of getting him to take part in those organized games which to a child of his temperament are perhaps the best preparation for a normal adult life. Dr. Helen Boyle herself admitted to being the non-athletic member of an athletic family, so that her remark carried weight when she urged that a dislike for games was not necessarily a sign of depravity. Health and athleticism, she pointed out, are by no means synonymous; work in an ill-ventilated room, and without opportunities for exercise, was a severe test of health, and it was not necessarily the athlete who survived it best. *Quot homines, tot sententiae.* Mr. H. M. Abrahams, the international athlete, so far from deprecating over-organization of games, would have every boy instructed individually in the mysteries of style, so that in later years he might develop into a seasoned player. But competition, he agreed, was an evil; too much emphasis was placed on success in games and too little on the effort which should be put into them irrespective of results. The use of the stop-watch and tape measure should be allowed to lapse, and those games encouraged which called for the co-operation of as many individuals as possible. Boys should apply themselves to a mastery of games in the same way as they were made to apply their minds to work. Recreation, in the view of Mr. Abrahams, is clearly a serious business. His brother, Dr. Adolphe Abrahams, spoke of the condition often described as "strained heart," and denounced it as a myth. A schoolboy's heart, he said, was as elastic as his stomach. But undoubtedly schoolboy athletes passed through a period of deterioration, or stagnation, from which they seldom recovered—often because they were told they had "strained hearts." A determined enough boy would pass through this stage, and become a successful performer later, but few had the necessary courage. Compulsory exercise he considered to be an invention of the devil; boys should only be taught to run, since running was the foundation of all games. Group Captain Martin Flack was not concerned with organized games, with stunted development of potential genius, or with running. In his view the boy should be taught to breathe properly, and more especially to use his lower ribs in the process. If, in addition, he performed such exercises as developed his abdominal muscles he was in a position to overcome the heavy disabilities of the upright posture. In man the main supply of blood was below the pump; the heart was not sufficient to pump the blood adequately round the upright body. Those games were valuable which gave the greatest amount of contortional activity, provided they were not played for too long at a stretch. In adolescence the vasomotor system was unstable, and doctors making physical examinations should allow for this fact. The position of affairs in France, according to Dr. Gustave Monod, was the exact opposite of that in England; the masters implored the pupils to refrain from dangerous sports such as running or jumping, since they were legally responsible for any injuries received by the boys in their charge.

Out of such diverse opinions it is hard to draw a conclusion. Is it possible that the individual is the best judge of his own exercise requirements? The energetic boy is not readily deterred from exertion, and the more placid type has possibly less need of exercise. We accept the behaviour of animals as natural, and believe them to fulfil their exercise requirements; it is at least conceivable that the intelligence of the human child is sufficient to inform him when it is necessary for him to run, and when he will profit by leisure.

EDUCATION OFFICERS AND SCHOOL MEDICAL OFFICERS.

DIFFERENCES of opinion, even serious disputes, have been known to occur between the principal officers of local authorities with regard to their respective spheres of action and of responsibility. Such disputes are not unknown even in other large offices with a number of important departments. They usually arise from a clash of personalities, and are continually being avoided by the exercise of tact and a wise acceptance of daily facts and practice. Yet from time to time in this way some question of principle or of essential practical importance is raised, and has to be faced, however reluctantly. During the years 1927 and 1928 the British Medical Association had to undertake a long correspondence with the Ministry of Health in order to safeguard the status of medical officers of health in relation to the clerks of county councils and town councils. This whole correspondence was reported to the Council on July 23rd, 1928, and the last letter from the Ministry, given the interpretations placed upon it in the final letter from the Association, appeared to afford as reasonable a solution of the fundamental difficulty as could be found. Lately, however, some directors of education have raised claims with regard to their position in relation to school medical officers which, if persisted in, will be strenuously resisted by the medical profession. Such resistance, if it becomes necessary, will be made not merely to uphold the dignity of the school medical officer, but in the interest of the efficiency of the service for which he is so largely responsible.

The importance of the position of the chief education officer of an authority is fully recognized. He must be chiefly responsible for co-ordinating the work undertaken by his department and for advising upon all its educational aspects; but the School Medical Service has other relationships also, in regard to public health in general, which must not be lost sight of. As we pointed out in an annotation on December 7th last (p. 1070), in certain areas attempts have been made to bring the work of the school medical officer under the control of the local director of education, and to deny him direct access to the local and central educational authorities. Further, in a circular issued by the Association of Education Committees (though not necessarily in this expressing the official opinion of the executive committee of that body) it is stated that the "school medical officer is the servant of the education committee. . . He takes his instructions from their chief executive officer and reports through him to the education committee." More recently still, these local directors have gone so far as to take exception to the action of the Chief Medical Officer of the Board of Education in communicating, otherwise than through them, with his colleagues of the School Medical Service in the local areas and asking them to send him reports on a medical matter affecting the efficiency of the service and the health of the people. This crescendo of claims is becoming too serious for toleration. To begin with, the school medical officer is not, in the ordinary sense, the servant of the education committee at all. He is the servant of the public, and has direct responsibility not merely to the local education authority but also to the Board of Education, if not to the Ministry of Health as well. In pursuance of this responsibility he has imposed on him the duty of reporting directly to the local education authority and to the Board, and this involves of necessity the right of uninterrupted and uncensored communication with both of these bodies. Official correspondence of the local educational authority as such with the Board should, no doubt, be conducted by the clerk to the authority or by the local secretary for education, as the case may be; but free communication and consultation between the school medical officer of any locality and the Chief Medical Officer of the Board (just as between any local technical principal officers and the chief technical advisers of a central department) is essential both for the advancement of knowledge and for the efficiency of the service.

As the President of the Board of Education said in a recent answer in the House of Commons, "It has been a practice of many years' standing for the Chief Medical Officer to communicate directly with his colleagues in the School Medical Service in regard to questions on which their professional opinion is desired." Is it to be understood that directors of education are now demanding that this shall not be done at all, or only by their leave? We hope that no more will be heard of any attempt to interfere with the position of any school medical officer in regard to the matters to which we have referred. Happily it is possible for efficient officers to be good colleagues.

DAWSON WILLIAMS MEMORIAL PRIZE.

At a recent meeting of the trustees it was resolved that the first award of the Dawson Williams Memorial Prize be made to F. J. Poynton, M.D., F.R.C.P., senior physician to the Hospital for Sick Children, Great Ormond Street, for his work on behalf of rheumatic children, particularly with regard to the establishment of special "rheumatic centres." It will be remembered that the establishment of this prize was due to a desire to commemorate the work of the late Sir Dawson Williams, for thirty years editor of the *British Medical Journal*, and in view of his special interest in paediatrics it was resolved that the interest accruing from the funds collected should be devoted to a prize in connexion with that subject, to be awarded every two years, or at longer intervals, in the discretion of the trustees, who are the presidents for the time being of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Royal Society of Medicine, the Section of Diseases of Children of the Royal Society of Medicine, and the editor of the *British Medical Journal*. The Dawson Williams Memorial Prize is open to any registered medical practitioner in the British Empire, and takes the form of a cheque for fifty guineas. It is hoped that the presentation of the prize to Dr. Poynton may be made by the President of the British Medical Association during the Annual Meeting at Winnipeg in August next.

CANINE DISTEMPER.

THE *Field* Distemper Research Committee, under the chairmanship of Sir Charles Martin, has just issued a supplementary report to that dated November, 1929, which we discussed in our issue of January 11th (p. 78). The present report is mainly devoted to an analysis of the various failures that have been observed since preventive measures were tried on a large scale. The preventive treatment consists of two inoculations; the first of a dose of *vaccine*, the second, given about a week later, of a dose of fresh *virus*. When the strengths of the two inoculations are properly balanced, no more than a slight febrile reaction should, as a rule, follow the dose of virus. In

some cases this reaction has been excessive. The committee considers that the vaccines have not been below standard, but, as a precaution, the manufacturers propose to employ even more stringent tests in future. Some failures have been due to reduction of the time interval; others to faulty technique. While, however, the method cannot be blamed for these there remain a few cases of failure for which the reason has not yet been discovered. The committee suggests that probably there will always be some exceptional cases of undesirably severe reaction to the virus even under the best conditions. In some cases injection of the vaccine-virus has not been followed by immunity, and such failure the committee attributes to the use of ineffective virus. It has recently been shown that some preparations of virus have diminished in potency by the time they have reached the veterinary practitioner; and it is proposed to try to prevent the recurrence of such defect by applying additional tests to all batches of virus issued in future. Some of the other cases of reputed failure have been shown to be due to diseases in no way connected with distemper; and in a few cases abscesses have developed at the site of inoculation. There is no reason, however, to doubt the success of the procedure in general, and the great majority of the 22,000 doses already issued have produced successful results in the animals treated. It is undoubtedly a practical method, though attended with obvious difficulties. The greatest are those inherent in the organization of production on a very large scale and the distribution and standardization of vaccine and virus. These difficulties are being overcome, and the introduction of more stringent tests by the commercial manufacturers (The Wellcome Laboratories) should do much to remove the very occasional issue of batches of virus (and perhaps of vaccine also) that are not absolutely up to standard.

CONTROL OF CONCEPTION.

BIRTH control is an important question, but not the all-important question which some of its advocates appear to assume. With a few notable exceptions the books and pamphlets written about it are characterized by a lack of clear thinking, are biased in judgement, being written under emotional influence rather than in accordance with scientific thought, and are, in fact, of the nature of propaganda rather than research. There are signs, however, of some improvement. It is beginning to be recognized that the medical problem involved is quite separate from those moral, economic, social, or even eugenic, problems which must form the major considerations in the controversy, and about which the medical profession can speak with no special authority. It is being acknowledged, too, that the medical problem itself is a relatively narrow one, and may perhaps be defined by three questions: Are there any effective means of controlling conception? Can it be truly said of any such measures that they produce no harmful effects? Along what lines may one look for new contraceptive methods having more desirable qualities and fewer defects than those used at present? These are clearly matters for research, and not for rhetorical or even dogmatic assertion. An attractive little pamphlet has recently been published by the Birth Control Movement Information Centre,[1] which gives in small compass an interesting history of the movement. While the ostensible purpose of the pamphlet is to be fair and unbiased, it becomes evident from page 24 onwards that its chief aim is to further a movement against departmental action taken by the Ministry of Health with regard to the teaching of contraceptive methods at recognized maternity and infant welfare centres. There are weighty reasons, political, administrative, and medical, for not using these particular centres for organized instruction in contraceptive methods. But the Ministry has always permitted the medical officers of such centres to refer women to private practitioners or hospitals, where they may obtain technical instruction, in cases where the avoidance of pregnancy seems desirable on medical grounds. The Ministry, moreover, is watching with interest the work of those relatively few so-called birth control clinics which have been established under voluntary auspices and are being conducted according to proper methods. One of these is the clinic working under the auspices of the Cambridge Women's Welfare Association. An extremely valuable volume entitled *Birth Control on Trial*[2] has just been published in connexion with the work of that association. It is a report by Mrs. L. S. Florence on the first three hundred cases dealt with at the clinic, whose subsequent histories have, with much care and as completely as possible, been followed up. This investigation and report deserve the adjectives which the author gives them, "dispassionate and honest," and the praise which Sir Humphry Rolleston gives the book in a foreword as "a model example of how the data should be obtained and marshalled." The book should be read by all interested in this subject. It would not be fair to quote its figures apart from the careful analysis to which Mrs. Florence submits them; it may be said at once, however, that they show a large proportion of failures, and falsify a large number of confident and wild statements that have been made by less competent and scientific observers. This report does not, of course, pretend to answer the questions in medical research that have been indicated above; though a serious attempt to answer them is being made by the Birth Control Investigation Committee, which, since its formation in 1927, has been engaged in a dispassionate study of the medical aspects of contraception. In effect Mrs. Florence's report is a powerful plea for such unprejudiced investigation. It may be held to establish two negative conclusions: that there is no contraceptive method which can be properly claimed as practically effective in the great majority of cases, and that there is not yet forthcoming any proof that the use of reasonable contraceptive methods produces results which are harmful in a considerable number of cases. It remains the duty of the medical profession to investigate these matters seriously and scientifically, and of clinics to keep full records of their cases and to follow up their results over an extended period of time, and then to publish them with the same care and in the same spirit as is shown in Mrs. Florence's book.

THE NEW FRENCH CANCER INSTITUTE AT VILLEJUIF.

ON March 17th M. Doumergue, President of the French Republic, opened the laboratories of the new Cancer Institute at Villejuif, a suburb a few miles south of Paris, laying the foundation stone of a hospital which is to be attached to this institute, and is to contain 150 beds. Some of the many steps which since the war have led up to this event may be briefly mentioned. In 1921 the Municipal Council of the Seine authorized Professor Gustave Roussy to start a small cancer service with out-patient facilities and a few hospital beds at the general infirmary of the Paul-Brousse Hospital at Villejuif. Between 1922 and 1925 several cancer centres were established in the chief provincial towns throughout France, but the lines on which these centres were organized were not altogether identical with those followed by Professor Roussy, who has described his guiding principles as the discovery of early cases, and the classification of the

[1] *The Birth Control Movement in England.* Foreword by Edith How-Martyn. London: J. Bale, Sons and Danielsson, Ltd. 1930. (5×7, pp. 31. 6d. net.)

[2] *Birth Control on Trial.* By Lella Secor Florence. With a foreword by Sir Humphry Rolleston, Bart., G.C.V.O., and an introductory note by F. H. H. Marshall, Sc.D., F.R.S. London: G. Allen and Unwin, Ltd. 1930. (Cr. 8vo, pp. 160. 5s. net.)

patients in various stages, supplemented by close co-operation between the Departmental and Communal public health services on the one hand, and general practitioners on the other. In the suburbs of Paris and in the three Departments, Seine-et-Oise, Seine-et-Marne, and du Loiret, he has organized a network, the threads of which are of three distinct patterns. These threads, which he describes as three successive *échelons* of growing importance, are: (1) free anticancer dispensaries, which are limited to the poor, and which are concerned with the discovery of early cases and the classification of the patients; (2) subcentres, which exist in certain towns provided with hospitals, and which deal with the classification and treatment of the patient; (3) the chief centre in Villejuif. The institute at Villejuif is provided with six groups of laboratories, the subjects of pathological anatomy, experimental medicine, physical and biological chemistry, tissue culture with cyto-biology, serology with bacteriology, and microphotography with cinematography being under the direction of specialists composing Professor Roussy's team. Work in these laboratories has proceeded during the past three months, the patients providing the observation material being provisionally accommodated in the old Paul-Brousse Hospital. It is Professor Roussy's intention to keep his hospital beds for patients undergoing treatment by operation or radiation, and not to clog these beds up with incurable cases which should, he considers, be distributed in different hospitals so as to avoid alarming the public. While the architecture of the institute has been largely inspired by Professor Roussy and his French colleagues, most of its equipment has been provided by Germany in the form of reparations in kind, under the terms of the Treaty of Versailles, to a value of about 2½ million francs. The institute is financed by the local authorities and the State; its close association with the Faculty of Medicine gives it a cachet and places it under a valuable scientific guardianship. The inauguration of Professor Roussy's institute was followed by a meeting of the International Cancer Union, which had its origin at Amsterdam in 1922. The second meeting was held in London in 1928. This, the third meeting, was attended by representatives of Great Britain, France, Germany, and numerous other countries.

PROGRESS OF CREMATION.

ON April 2nd the Cremation Society of England decided to shorten its name by omitting the last two words. Most of the influences that discourage the adoption of cremation in this country have been mentioned in previous references to the subject in these columns. The active opposition and prejudice against this method of disposing of the dead, its restriction to the well-to-do, the wide-spread apathy, the stringent legal requirements, and the popular notion that cremation is an expensive business have been matters of recent inquiry by the council of the society. In spite of these obstacles the movement continues to progress. The society reports that 4,353 cremations were carried out in Great Britain during 1929. This represents an increase of 25 per cent. over the figure of the previous year. More significant is the fact that there was a general increase throughout the country, especially in the smaller crematoriums. Cremations at Leicester increased by 103 per cent. Two crematoriums were opened, in Edinburgh and in Guernsey; others are being completed at Brighton and Nottingham; and additional facilities are contemplated by the municipal authorities of Leeds and Glasgow. Much of this growing national sentiment, which has led the society to abbreviate its title, has arisen spontaneously from personal conviction. Economic pressure, however, is likely to be a more potent force in removing the more obvious disabilities. Burial accommodation is rapidly diminishing in many parts of the country, particularly in populous districts. The council states that there is ample evidence that local authorities are being compelled to consider the provision of crematoriums to solve this problem. At the Health Congress last autumn the question of preparing more effective propaganda was discussed with the Central Council for Health Education, to which the society is affiliated, and posters have been designed for display during health weeks and similar occasions. Renewed representations were made to the Home Office by the Federation of Cremation Authorities for amendment of the statutory regulations, and the hope is expressed that the Ministry of Health will consider this year the advantages of cremation to the State. New offices have been acquired by the society at 23, Nottingham Place, W.1.

WILLIAM HENRY WELCH.

THE eightieth birthday of Professor William Henry Welch will be celebrated in Washington on Tuesday next, April 8th, and a broadcast of the ceremonies will be relayed from the London Regional Station at 5 p.m. In 1224, when the bequest of a rich American, Johns Hopkins, led to the foundation of a new university in Baltimore, Dr. Welch was chosen first professor of pathology. Mainly through the genius and enthusiasm of Welch, Osler, and Halsted, the new medical school rapidly rose to the first rank, and for more than a generation it has been the goal of advanced students and research workers from all parts of the world. Dr. Welch, who was later director of the School of Hygiene at Johns Hopkins University, and is now professor of medical history there, has lived to see the educational ideals for which he fought universally adopted. On the same day as the ceremonies in America, an address, with lantern illustrations, on Professor Welch's life and work, will be given at 4 p.m. at the London School of Hygiene and Tropical Medicine, Keppel Street (Gower Street), W.C., by the director, Sir Andrew Balfour. A cordial invitation is extended to all who are interested.

INTERNATIONAL SOCIETY OF ORTHOPAEDIC SURGERY.

THE first congress of the International Society of Orthopaedic Surgery will be held in Paris, under the presidency of Sir Robert Jones, from October 2nd to 4th next. The subjects chosen for discussion at the congress are: (1) The treatment of congenital dislocation of the hip after the age of 15 years: on this subject America, Germany, Great Britain, and Italy have been asked to supply speakers. (2) The treatment of injuries in the region of the wrist joint, which will be discussed by representatives of France, Holland, and Sweden. The officers of this society are: President, Sir Robert Jones; vice-presidents, Professor Vittorio Putti of Bologna and Dr. H. Gocht of Berlin; secretary-general, Dr. Delchet of Brussels; and treasurer, Professor A. Maffei of Brussels. The secretary of the first congress is Dr. Albert Mouchet of Paris.

WE regret to announce the death, on March 29th, of Dr. John Yule Mackay, principal and formerly professor of anatomy, University College, Dundee, and for the past twenty-eight years representative of the University of St. Andrews on the General Medical Council.

SIR GEORGE NEWMAN, Chief Medical Officer to the Ministry of Health, will give four lectures on "How England learned to control disease," at Gresham College, Basinghall Street, E.C.2, on April 8th, 9th, 10th, and 11th, at 6 p.m. Admission is free.

LORD BALFOUR AND THE PROGRESS OF MEDICINE.

BY

SIR WALTER FLETCHER, K.B.E., C.B., F.R.S.,

SECRETARY OF THE MEDICAL RESEARCH COUNCIL.

THE public tributes lately paid to Lord Balfour as a political leader and as a great servant of the State have inevitably left in relative shadow the services he gave throughout his long life to the promotion of education within the country and to the advancement of knowledge by research. These are not forgotten, and that they should now be passing relatively unacclaimed is in itself but a measure of the great range over which his private interests and public work extended. It is only the passage of time that can bring into sight the true proportions and relative values of all he did. It is not very daring even now to prophesy that as contemporary views of party history are adjusted and fade, as records now confidential become known, the future generations will find cause to believe that of all the services Lord Balfour gave to England none have a higher claim on their gratitude or contributed more to their welfare than his unswerving faith in the value of education and of knowledge, and the practical expression he found means of giving to it.

No English statesman of modern times, with the possible exception of Lord Haldane, has ever had the same grasp as Lord Balfour of the methods by which natural knowledge is enlarged and more detailed information of the growing points in its chief branches. He had quite exceptional opportunities given to him by birth, by his political career, by his almost unique position in society, and by his high skill in argument, whether public or private, of aiding any great cause he had at heart. His political life, party warfare, the irregular claims and opportunities for constructive legislation, and, nearer the end, the great tasks laid upon him during and after the war, all these kept him from giving with any continuity and completeness the service he was always eager to give to the progress of knowledge and to its more effective use for the general good. Nevertheless, in uncountable ways he used his powers at every opportunity to serve education and research, to deal a stroke for them at this point, to remove an impediment at that. Only as time passes can it be seen how great in sum has been his achievement within those fields.

The debt that medicine in particular owes to Lord Balfour is certainly hardly measurable now, but it may assuredly be said that no great statesman can be named in modern history as having done it greater service. The benefits we owe to him are both general and particular. In general, medicine has drawn increasing strength, like every other field of learning, from the services Lord Balfour gave to education in the country as a whole. This is not the place in which to speak of those. We may well remember, however, that our still youthful system of modern universities, including, of course, their medical schools, in England, Wales, and Ireland, almost all of it framed within the present generation, rests largely upon the efforts of Lord Haldane, with indispensable aid from Lord Balfour, and that no chapter in recent political history is more creditable than that in which those two men carried forward this great work in spite of party antagonism and behind its set scenery. The national system of public secondary education, the soundness of which is the condition of health for any national university system, this, of course, was the work again, more conspicuously and directly, of Balfour, aided by that great public servant Sir Robert Morant.

Lord Balfour's specific services to the progress of medicine as such, and outside this general sphere of education, have been thrown into shadow, even more than his services to physical science, by the glamour of his personal and political gifts. J. Bale, Sons and Movement in with Lord Rayleigh kept him in easy h of physical science that he followed with such personal interest, and he played a leading part in the foundation of the National Physical Laboratory during the Premiership of his uncle, Lord Salisbury. Many of his public utterances and writings, of which the brilliant address he gave as President of the British Association at Cambridge in 1904 is a good example, made the educated public well aware of his informed sympathy with the progress of physical science, and the fascination it had for him in its relation to philosophic thought. But he had an even closer family tie with the biological world. His brother Francis, for whom the chair of animal morphology was especially created at Cambridge, where the beauty of his short life and great work are still a living tradition, may be called the founder of comparative embryology. It was in tribute to Lord Balfour and his family, many years after his brother's untimely death in the Alps, that the Balfour chair of genetics at Cambridge, first held by Bateson, was endowed. He followed the progress of biology at all its chief points of active growth with at least the same eagerness and enjoyment as he drew from the developments of physical science. There was certainly no aspect of biology which had a stronger appeal for him than that of its bearing upon the hopes of human progress and upon the immediate merciful work of the medical profession. At every period of his life he showed his friendship for the progress of medicine and the medical sciences; and the friendship, active and sustained, of a man with his gifts and opportunities could not have failed, and did not fail, in spite of his manifold preoccupations of other kinds, to bring aid of far-extending value to the causes that "medicine" represents.

During most of his life he had no time to give public service in this direction except by occasional speeches on behalf of institutions or societies. His speeches, however, had an educative value of exceptional kind. His were not the deliverances of the prominent public man giving patronage to science in a speech framed for him upon the occasion. They were speeches made *ex tempore* from the briefest possible notes, that showed personal knowledge of the essential problems in view and of the methods being used to solve them. A good example may be found in his speeches, beginning more than a quarter of a century ago, that were made on behalf of the Imperial Cancer Research Fund. His knowledge and clear vision allowed him not only to understand the point of view of the scientific workers but to explain it to the public at large and to the laymen whose support was necessary. His aid then must be counted as contributing greatly to the enlightened spirit in which so much valuable work for that Fund has been done for many years in the face of a good deal of pessimism from the profession and much clamour for quick results from an impatient public. Looking back now with our present knowledge, we can see that Lord Balfour was then taking the true vision and giving wise counsel, and not a word that he said in those early years appears now to be out of place or unjustified. So it was in his speeches on behalf of many other interests, whether upon tuberculosis during the early years of the century, when public attention was focused upon it and sanatorium treatment was being actively developed, or upon eugenics, or upon bacteriology, that he had seen born as a science, or upon the importance of the study of tropical medicine for the Empire. Above all, and at every point, he threw his influence steadily into the movements, whether public or private, that made towards the better encouragement of scientific research in this country. He did much behind the scenes, and he spoke upon this matter publicly and often. Nowadays it is becoming not uncommon for public men to understand the value of research and to work for its aid. But thirty years ago or more there was no Minister of the Crown who would or could have said, as he did in 1898:

"I have all my life been an ardent believer in a cause which is often laughed at—the cause of the endowment of research. In that cause I most firmly believe, and I think there is no branch of knowledge in which it may find a more useful field of application than in that of advancing medical knowledge. It is wonderful to think how the public are prepared to pay, and in my opinion rightly prepared to pay, for the services of those whose clerical genius, whose power of absorbing all that is practically useful

in the knowledge of their day, whose bedside genius—if I may so describe it—demands, and ought to have the fullest recognition—it is wonderful, I say, how the public are prepared to pay for that kind of genius, but apparently put aside with indifference the not less essential kind of genius which deals with the progress of knowledge and the furtherance of invention. This is not selfishness; I think it is latent imagination. The work of the medical practitioner is seen at once; its value can be immediately appreciated; but he who spends his life in the pursuit of the secrets of Nature, working in his laboratory, may very often receive no public recognition at all during his life, except from that restricted circle of experts who alone, after all, are capable of forming any valuable estimate as to its merits,"

and it was just before he became Prime Minister four years later that he said:

"I do not believe any man who looks round the equipment of our universities, of our medical schools, and other places of education, can honestly say in his heart that we have done enough to equip research with all the costly armoury which research must have in these modern days. We lag behind—we, the richest country in the world, lag behind Germany, France, Switzerland, Italy. Is it not disgraceful? Are we too poor, or are we too stupid? Do we lack the imagination required to show what these apparently remote and abstract studies do for the happiness of mankind?"

and he went on to say:

"It is the result of my unfortunate profession that I am constantly engaged in discussions and in conflicts which at the worst have a party significance, and at the best have but a national significance. The cause I plead now is not the cause of a party nor the cause of a nation—it is the cause of mankind at large. Every discovery which is made in the laboratory in Germany, France, or Italy is the possession, not of those countries, but of the whole world. Let us not be backward in this great international competition, which surely may be said, in some way, to balance that more costly and destructive competition in armaments and, it may be, in commerce."

Inasmuch as his "unfortunate profession" prevented him through most of his long life from giving more than his powerful words and great influence to promote medical advance, we must count it a very happy stroke of fate that brought him at the age of 71, after his long political life and his later services in making war and making peace, to be Lord President of the Privy Council, and in that office to be responsible to Parliament and in the Cabinet for the greater part of the State aid now given for the support of scientific research. It would not be hard to guess, and indeed I have heard him declare himself, that no part of all his public work, immense as its range had been, had brought him so much matter for personal interest or had seemed to him to be of more importance. In each of the two research Departments falling directly under him—the Department of Scientific and Industrial Research and the Medical Research Council—his active personal interest from that beginning, now ten years ago, is passing into legend. On the very day after he assumed office, a tall gentleman called unexpectedly at the not very obvious offices of the Medical Research Council in Buckingham Street and announced himself as Mr. Balfour. He had called, he said, to see "whether there was anything he could do to help." The Council had worked previously under some six or seven Ministers, variously eminent, but none, I think, had ever made himself aware of the geographical position of the office. In like manner he paid, as Minister, repeated personal visits to the sister Department. Need explanation be offered for the affectionate devotion his courtesy and simplicity won from all his subordinates?

In 1922 he resigned with the Coalition Government and assumed private life. In 1924 Mr. Edward Wood, now Lord Irwin, resigned the chairmanship of the Medical Research Council on his appointment to be Viceroy of India. The appointment to the vacancy on the Council fell to Lord Curzon. He desired a representative of the Council to seek the opinion of Lord Balfour, who indicated that he himself would be willing to join the Council and become chairman, if Lord Curzon could not see his way to a better appointment. Never, we may suppose, was an appointment more confidently made, and never, certainly, was any so welcome to the Council he joined. From that time, and for nearly five years, until his health failed, he regularly attended meetings of the Council and gave the most ready sympathy and eager help to their work at all times and in every way open to him. Upon Lord Curzon's death in 1924 Lord Balfour joined Mr. Baldwin's Ministry and again became Lord President of the Council. As is now well known, he made the Medical Research Council aware that he so much enjoyed seeing their work at first hand that, unless the point were raised by others, he was prepared himself to connive at a situation in which he remained chairman of a body that was advisory to himself as Minister to the Crown. He continued to serve the work of medical research in both capacities until the Ministry fell last summer, and he resigned his chairmanship of the Council on the ground of ill health shortly afterwards.

Lord Balfour's knowledge of the research work done on behalf of the two research organizations under him had made him increasingly aware before 1924 that some better machinery was needed for bringing the results of investigation, when attained, into more effective application in human affairs, and that this machinery must include more effective modes of consultation between separate administrative Departments or Services on the one hand and the men with first-hand scientific knowledge on the other. When Mr. Baldwin announced in Parliament after Lord Curzon's death that Lord Balfour was to succeed as Lord President, he said that he was to be entrusted with the special task of improving the machinery for bringing the results of scientific work into their proper relation to statecraft. Almost immediately after his appointment in 1924 Lord Balfour, who, as Prime Minister a quarter of a century before, had established the Committee of Imperial Defence, proceeded to set up a closely analogous machinery for civilian affairs as the Committee of Civil Research. Under this committee, as under its military counterpart, there sprang up progressively a number of subcommittees, each constituted with a single eye to the promotion of some special object, for the gaining of which scientific knowledge and administrative art must go hand in hand. All these subcommittees reported confidentially to the Cabinet, and not a tithe of the work which has been done is familiar at present to the public. It is now increasingly apparent as the facts have become known that no single agency did more to save the country in the war than the timely work of the Committee of Imperial Defence. It is not a rash speculation to guess that the next generation will realize that no single agency may have done more to save and develop the Empire than Lord Balfour's Committee of Civil Research—if we may assume that its realities, unlike its name, are to be retained in what has been re-christened by his present successors the Economic Advisory Council. If the records could lie open it would now be seen what effective work Lord Balfour had done at the extreme end of his long life for the advancement of science and for the enrichment of its powers to help the country. In no branch of science has this been more evident than in the biological sciences, and especially in those medical sciences serving the well-being of human life and industry in tropical parts of the Empire.

To Lord Balfour himself we can hardly apply more fitting words now than those which he used himself of Lord Salisbury when paying his obituary tribute in the House of Commons: "It is impossible to form a full and fair judgement of the policy of any statesman until his career be run and until the secret documents, by which alone he can be judged, become common property. . . . It is not until the controversies in which we have been engaged have lost all living interest and have become the property of the student in history that our children will be able to judge how great and how beneficent was the part he played in the history of this country." It will be in large part due to his own efforts for education if our children come to see, and more clearly than our own generation has seen, that place which natural knowledge should take in the right guidance of the State, and in proportion as they learn that lesson they will pay tribute to Lord Balfour's life and work.

PREGNANCY DIAGNOSIS STATION.

REPORT ON FIRST YEAR'S WORKING.

BY

F. A. E. CREW, M.D., D.Sc., PH.D.,

DIRECTOR, ANIMAL BREEDING RESEARCH DEPARTMENT, UNIVERSITY OF EDINBURGH.

Introduction.

A LITTLE more than a year ago my colleague Dr. B. P. Wiesner convinced me that for several reasons it was desirable to examine on a large scale the pregnancy diagnosis test of Zondek and Aschheim. Out of this suggestion emerged the Pregnancy Diagnosis Station, the conduct of which has very largely been in hands of Dr. E. M. Robertson, working under the supervision of Dr. Wiesner.

The station, attached to the Animal Breeding Research Department, was opened a year ago. At that time a certain amount of work had been done on the accuracy and applicability of the Aschheim and Zondek reaction (A.Z.R.), but this work was almost entirely restricted to experimental material, and to cases selected in various respects. At the station, however, the test had to be applied under routine conditions and on unselected cases. It was intended that, should the results prove favourable, the work of the station would continue so as to make its services available for hospitals and practitioners. It is obvious to everybody who knows the technique of the test that it has to be carried out at some selected centre where the keeping of animals on a sufficient scale is possible; it cannot be carried out anywhere and everywhere.

The station has had to deal with a considerable number of specimens sent in for diagnosis from hospitals and doctors in all parts of Great Britain and Ireland. It cannot yet be decided what actual percentage of the cases was diagnosed correctly, since the findings of the station have to be controlled by clinical diagnosis performed by the doctor, and such control information has to be communicated to the station by him. In many cases this confirmation has not yet been received, and so a full account cannot be given. However, this report at the end of the first year may fulfil a double purpose by conveying an impression of the preliminary results, and by explaining certain limits of the test as well as sources of misunderstanding.

The Test.

Aschheim and Zondek have fully described their technique, and more recently Allen and Dickens published a full account of the test. The method of carrying out the test at the Pregnancy Diagnosis Station corresponds almost exactly to the Aschheim and Zondek technique, except that naked-eye detection of blood points in the ovaries is relied upon entirely, and the third pituitary reaction of Zondek and Aschheim is neglected. Microscopic examination is not found necessary, because a minimum positive reaction produces an easily recognized blood point formation. If, however, the blood points are small and sunk in the ovary, and at the same time corpora lutea formation is marked, the blood points may be distinguished by holding the ovary up to the light, when they appear darker than the densest of the corpora lutea. Some investigators when in doubt press the ovary in glycerin between two cover-slips and examine under a lens. For this test, as the results show, the naked-eye technique is not less accurate than the microscopic. By abandoning microscopic examination the whole procedure is made simple and rapid. However, if there is any doubt as to the presence of blood points, a fresh specimen of urine is obtained, where possible, and the test is repeated.

In order that no mistakes may arise during the handling of specimens, and that the recording be as accurate as possible, a special record book is used. Each sample on arrival at the station is at once filtered into a numbered bottle, and any particulars regarding the specimen are entered in the record book, opposite the corresponding number. For each entry in the book there are two pages. The first of these is so printed and perforated that from it are available two numbered labels, one for the urine container and one for the mouse cage; a record card for filing; a "result" letter; a "follow-up" letter; and an injection record card. All entries are duplicated on to the second page, which remains in the book. As soon as the results become available the "result" letter is sent off to the "sender"—at the latest within six days of the arrival of the specimen (the test actually takes about 100 hours). In an attempt to supply a result in very urgent cases, certain experiments have led to the adoption of an emergency test. It was found that by using larger doses of urine a result could be obtained within sixty hours. In cases of great urgency such a procedure is adopted, but a control test with the standard method is also carried out. If the emergency test turns out to be positive, then a positive result is returned at once; a negative result, however, is withheld until the second test is completed. Such a modification had been suggested by the originators of the test.

The station requires that two ounces of fresh morning urine, in a sterile container strong enough to withstand the dangers of transport, be sent along with a few notes on the case, giving the name, age, parity, date of the last menstrual period, menstrual history, history of any severe constitutional disturbances, and also such information as will supply a reason for sending the urine within twenty-eight days of the last menstrual period.

Limitations and "Errors."

It has been found that in about 1 per cent. of cases the sample of urine kills the experimental animals, and so no result is forthcoming. In these cases, where possible, second and third specimens are tested, generally without success. The cause of death of the mice seems to be different for different specimens of urine. The prevention of bacterial action or the elimination of toxic elements has not been practised in the station, because, so far, no simple method for doing so has been devised. There is not, so far, a sufficiency of clinical detail or of data from the examination of such urines to allow of an opinion being formed as to the nature of the toxicity. It is hoped that before long a solution to this problem will eliminate one source of weakness in the test.

On account of the nature of the organization of the station, errors arising from the human element are reduced to a minimum and can be neglected. Two factors which must contribute to the error are (1) unsuitable conditions of the urine—for example, dilution; if not a morning specimen the urine may be insufficiently concentrated to give a positive result; this is unusual; (2) lack of complete and accurate control of results.

It must be pointed out that as far as the station is concerned the control is entirely in the hands of the "sender" of the specimens, and for the following reasons cannot be as reliable as it would be were the test carried out on a purely experimental basis: (1) the doctor has to depend on the uninitiated patient for many clinical details, information about, and description of, abortions, etc.; (2) microscopical examination of pathological specimens is not always possible. For an adequate control both these items are necessary in many cases.

The Results.

In all, 840 cases have been dealt with from the inception of the station up to the end of January, 1930. In 10 cases the urine was insufficient in amount, or lost in transit, and therefore no test was possible. Thus 830 tests have been carried out, but in 24 cases "no result" had to be returned on account of the toxicity of the urine causing the death of the test animals. Of 805 cases diagnosed at the station the report only deals with the 460 about which control information has so far been received. It is obvious that of necessity such information is generally some months in arrears, hence the comparatively small number of controlled cases.

Diagnosed at the station as:		
Positive	...	286
Negative	...	174
These have been controlled thus:		
Correct	...	446
Incorrect	...	14

It is at once seen that with the 14 (so-called) cases of incorrect diagnosis the results show an error of 3.04 per cent. However, this figure, having been influenced by various factors, only represents an apparent error, and so provides a misleading impression of the value of the test

In order to judge this value correctly it is necessary to discuss certain limitations of the test and to analyse the factors which have adversely affected the results.

Examination of Results.

As this biological test for pregnancy is of recent origin and quite unique, it is natural that some time must elapse before practitioners become familiar with it and with the principles involved, and thus realize the importance of sending case-notes to the station. Only scanty—if any—notes have been received, and the classification and analysis of cases has frequently been difficult. However, an examination of the results has been attempted. A short discussion of the basis of the test will make for a clearer understanding of these results.

It will be remembered that the A.Z.R. is based on the occurrence in the urine of large amounts of at least one gonadotrope hormone which normally (that is, outside pregnancy) is only found in the anterior lobe of the hypophysis. During pregnancy it is apparently produced by, and certainly found in, the placenta: and in associated conditions, such as *hydatidiforma* mole, it is also produced in large quantities. The presence of large amounts of this substance in the urine is therefore not necessarily a sign of the presence of a foetus. However, its production in large amounts, in conditions unassociated with pregnancy, is apparently rare. Thus the term "pregnancy" is used, in communications from the station, qualified by the words "does exist" or "does not exist," according to whether the test shows a positive or negative result. Of course, one could refuse with some justification the term "pregnancy" in certain cases if one defines pregnancy as the time during which an ovum is actually developing in the maternal organism. A positive A.Z.R. is a sign that the body contains at the time highly active sources of those hormones, such as the placenta or its derivatives, or some other abnormally active tissue. The test has been proved to show a positive reaction in cases of retained adherent fractions of the placenta, incomplete abortion, hydatidiform mole, and chorion epithelioma. The test is also positive for a few days after normal parturition and complete abortion. On the other hand, the presence of an inactive (dead) placenta is not associated with the production of this hormone, and so the presence of a dead foetus and placenta does not lead to a positive result.

The distribution of positive and negative results among the 14 so-called incorrect diagnoses was as follows:

No.	A.Z.R.	Doctor.
13	−	+
1	+	−

Details of these cases are seen below in tabular form.

No.	Test	Dr.	Details.	Remarks.
5	−	+	Six months' amenorrhœa. Abdomen 3 months pregnant. *No P.V. Doctor*	? Dead ovum.
10	−	+	62 [illegible]	Dead ovum.
12	−	+	Macerated foetus delivered at 12 hours after urine taken	Dead ovum.
13	−	+	Same as 12	
2	−	+	No details	
11	−	+	No details	
14	−	+	No details	
8	−	+	60 days after L.M.P.	
9	−	+	36 days after L.M.P.	
6	−	+	45 days' amenorrhœa. Miscarried 1 month later	? Deficiency causing miscarriage.
7	−	+	41 days after L.M.P. 2 years ago had 1 ovary removed and both tubes excluded. Abortion 15 days after time of test	? Deficiency causing abortion.
3	−	−	Lactating. Baby 8 months. Repeated 2 months later. Positive	Lactating. ? Pregnancy came later.
4	−	+	43 days after L.M.P. Repeated 3 months later. Positive	
1	−	−	No menstrual irregularity. Breasts active. Young girl. Repeated 3 weeks later. Negative	? Endocrine disturbance.

The above table reveals that 5, 10, 12, and 13 were cases in which, at the time of taking the urine, the foetus was dead and the pregnancy ended.

Cases 2, 11, and 14 cannot be discussed, as no details of the histories were supplied.

Apparently the results given in Cases 8 and 9 were incorrect, but here again details of the subsequent course of each case are lacking, and so the station is left in doubt. Case 1 seems to have been mis-diagnosed, as the doctor attending the case says that there was no possibility of an abortion having taken place between the time of test 1 and test 2. It is to be noted that Case 1 is the only one where a positive result was questioned.

Cases 6 and 7 are associated with premature interruption of pregnancy some short time after the test was found negative. Recent findings show that the pregnant state and the maintenance thereof is necessarily associated with a great production of the hormones mentioned above, and it follows that if the production is insufficient then the pregnancy comes to an end. This seems to be exemplified in Cases 6 and 7, the negative result meaning that there is not sufficient hormone in the urine to affect the mouse ovary, and this deficiency in the maternal organism is such that pregnancy cannot go on. Thus abortion is precipitated.

It seems obvious from the details of the table that, of the 14 cases labelled incorrect, at least 4 cases (5, 10, 12, and 13) were so designated by the "sender" through a misunderstanding of the test. These cases were probably correctly diagnosed in so far as the test detects the presence of active products of conception. This means that the apparent percentage error of 3.04 is reduced to a real error of 2.2 per cent., and, were details available of Cases 2, 8, 11, and 14 this figure might be still further reduced.

Special Analyses.

The average age of pregnancy diagnosed was 69 days: 78 cases were within sixty days of the last menstrual period, and of these 2 were within nineteen days of the last menstrual period, and 2 within eight days of the first lapsed menstrual period. In 6 cases the history was more definite, and of these 5 were within forty days, and 1 within twenty-eight days of the last coitus. It was also known in these cases that menstruation had been regular up to the time of that coitus.

In order that an idea may be formed as to the type of case in which the Aschheim and Zondek test is sought notes on a few cases are given.

Correct Negative Diagnosis.

(C. 4.) Married, aged 34; diminution of menses but no actual cessation. ? Two months pregnant or menopause.

(C. 5.) Unmarried; forty-seven days since last menstrual period; patient stout, breasts enlarged, uterus retroverted, cervix soft, some morning sickness. ? Pregnancy or menopause.

(G. 2.) Married; forty-seven days since last menstrual period; last baby six months ago.

(I. Z. 6.) Single, aged 22; sixty-two days since last menstrual period.

(I. Z. 9.) Married, aged 33; operation for ruptured ovarian cyst, uterus large. ? Pregnant.

(I. D. 4.) Married, aged 36; one hundred and ten days since last menstrual period; 3-para; patient very nervous and convinced she is pregnant; has had several slight "shows."

(3. F. 2.) Married, aged 42; one hundred and five days since last menstrual period; 2-para; breasts enlarged; patient very stout and no fundus felt. ? Menopause or pregnancy.

(4. E. 8.) Married, aged 44; fifty-three days since last menstrual period; 1-para; menstrual history previously regular. Patient contains a fibroid which might require surgical treatment.

(4. H. 8.) Married, aged 46; seventy days since last menstrual period; 5-para; uterus enlarged by one or more fibroids, one part resembles the pregnant uterus in softness and size.

(6. K.) Married; some sickness for three to four months; vomiting in the pelvis; said she felt foetal movements; no amenorrhœa. A.Z.R. negative, and abdomen opened and tuberculous ovary found.

Correct Positive Results.

(I. 9.) Single, aged 22; sixty-two days since last menstrual period; patient becoming stout; question of pregnancy difficult to settle.

(I. E. 1.) Married; seventy-seven days since last menstrual period; 2-para. Lost child five months ago. Is vomiting frequently and losing weight.

(1. F. 0.) Married; forty-one days since last menstrual period; 3-para; sickness with enlargement of the breasts; not to be relied upon as patient wishes to become pregnant.

(2. E. 4.) Married, aged 25; fifty-six days since last menstrual period; 1-para. ? Retroverted gravid uterus.

(2. F. 7.) Married; sixty days since last menstrual period; has chronic salpingo-oöphoritis; doctor thinks pregnancy unlikely.

(2. I. 6.) Married, aged 40; seventy days since last menstrual period; 2-para; uterus abnormally enlarged. ? Fibroids or fibroids and pregnancy.

(3. E.) Married; fifty days since last menstrual period; severe phthisis.

(3. E. 2.) Married, aged 24; seventy-four days since last menstrual period; very severe vomiting. ? Hyperemesis.

(5. C. 4.) Regular menstruation up to the time of operation for haemorrhoids; since operation (three months) had amenorrhoea. ? Pregnancy.

(5. I. 1.) Single; fifty-six days since last menstrual period; had previously long period of amenorrhoea—up to ten weeks.

The test shows an error of 2.2 per cent. It has been suggested that this figure is not exceeded in the ordinary run of practice with the usual clinical methods. That may be so, but from the type of case sent for diagnosis it is fairly obvious that the station deals with cases which normally form the small percentage not easily diagnosed by purely clinical methods.

The biological importance of the test was obvious from the beginning, and it was for the station to show whether it could be applied on a practical basis, and at the same time maintain sufficiency and accuracy. Experience in working the station for one year shows that the test is quite capable of practical application under suitably organized conditions, and it is hoped that the report demonstrates that the test, if so applied, is a valuable diagnostic aid.

Conclusion.

The work of the station will be continued. During this first experimental year the fees were kept as low as possible, but it was found that the expenses were not covered, and a deficit was incurred. It has now been decided, therefore, that the fees will have to be increased as from March 7th. For private practitioners the fee will now be 10s. for each diagnosis; for hospitals and infirmaries 3s. It is hoped that the expenses will thus be covered and that a further increase will be avoided.

England and Wales.

Birmingham General Hospital.

THE 150th anniversary of the opening of the General Hospital, Birmingham, which occurred last year, was commemorated by a special service in the chapel, and subsequently by a choral service in the cathedral church of St. Philip. At the anniversary dinner in October members of the medical staff were the guests of the senior physician and senior surgeon. In the report for 1929 the executive board expresses the hope that it may be possible to start building the new hospitals centre at an early date. The scheme was outlined in the *British Medical Journal* of February 8th (p. 255). Co-operation with the Queen's Hospital has been strengthened by the interchange of liaison officers between the medical committees of the two institutions. The wards and casualty departments in course of erection on St. Mary's site are expected to be ready for occupation in the autumn. This extension has reduced the annual income of the hospital by over £2,000. As a result of a broadcast appeal in the early part of the year 600 mg. of radium were purchased by the hospital, which has now over thirty beds available for the radium treatment of cancer. Progress may [illegible] this department was recognized by the National Radium Commission in selecting the General Hospital as a centre for treatment and research. The experiment of receiving paying patients is reported to have been entirely successful. In-patients during the year numbered 7,057, an increase of 407. Out-patients increased from 55,005 to [illegible]. In the social service department 134 children were helped in various ways. A convalescent home had been opened for children under 3 years of age; a record the forty-[illegible] a "follow-up" le[illegible]

fourth annual report of the Jaffray Branch Hospital, 368 patients were treated in 1929, 65 less than in the previous year. The number of beds is now sixty-five, which includes four cots.

Council Hospital Accommodation in London.

Under the Local Government Act there have passed under the direction of the Central Public Health Committee of the London County Council eleven fever hospitals (6,771 beds) hitherto directed by the Metropolitan Asylums Board; three "river hospitals" at Dartford (1,898 beds) for fever and small-pox; one hospital for ophthalmia neonatorum, marasmus, and zymotic enteritis (60 beds); two institutions for venereal diseases (103 beds); nine institutions for tuberculosis (2,057 beds); two for sane epileptics (705 beds); and five for children (1,992 beds). In addition, thirty Poor Law hospitals and infirmaries (17,022 beds), hitherto directed by boards of guardians, have come under the committee's control. To the Mental Hospitals Committee there have been transferred from the Metropolitan Asylums Board five hospitals or colonies (10,387 beds). In addition to the provision made for the treatment of sick persons in what have hitherto been known as Poor Law Hospitals, there is accommodation for sick persons in institutions which provide also for the able-bodied poor. The Central Public Health Committee finds the questions involved in the separation of the able-bodied poor from the sick, especially in view of the varying degrees of sickness, very difficult of settlement. It is thought desirable that two types of hospital should be recognized, one for the acute sick (including patients under continuous medical or surgical treatment, maternity patients, and mental patients), and the other for the chronic sick (including patients under institutional treatment because they are suffering from some chronic disease, and also aged and infirm persons requiring medical and nursing attention). Careful consideration has led to the belief that the present accommodation for the acute sick may be inadequate for future needs. In the institutions which now come under the Council's control there is what is described as a heterogeneous mass of chronic sick and aged and infirm persons, and it is not easy to define the degree of infirmity or disability in this group which places a person technically among the "sick." There can be no clear line of demarcation between the healthy aged and the infirm aged, the one gradually passing into the other; although the borderline case may not be technically "sick," it requires as much medical and nursing care as many serious maladies. The committee feels that there can be no doubt that a hospital standard of care and attention should be applied to all persons suffering from chronic disease and also to the aged and infirm. It is therefore proposed to allocate twelve institutions comprising 9,661 beds, for the chronic sick—namely, the Fulham, Hammersmith, Kensington, Holborn, St. Pancras, Shoreditch, City of London, Hackney, Stepney, Camberwell, Greenwich, and Lambeth institutions. The accommodation controlled by the Central Public Health Committee and that controlled by the Central Public Assistance Committee here overlap. A certain amount of accommodation for "healthy" cases remains in hospitals under the direction of the former, and for chronic sick cases in institutions under the direction of the latter, but it is stated that time will be necessary for reorganization and re-classification, and that the present allocation must be regarded as provisional only.

Royal Free Hospital.

At the annual court of governors of the Royal Free Hospital, on March 25th, under the chairmanship of Lord Riddell, the American Ambassador paid a tribute to the humanitarian work of the hospital. Its policy, he said, considered the actual needs of every person requiring treatment, whatever his status or race. He also referred to the service the hospital had rendered to Americans in London. Most of the matters discussed in the 102nd annual report have already been mentioned in these columns. The foundation stone of the Eastman dental clinic was laid by the Prince of Wales last April, and the building is expected to be ready in May. Arrangements

for its equipment are being made by Dr. Burkhart, director of the Rochester Dental Dispensary. Sir Albert Levy's gift of £50,000 has enabled the committee to proceed with the construction of the lower and ground floors of the Queen Mary wing, designed to rehouse the maternity department; this is the first part of the central extensions for which a sum of £5,000 was allocated by the trustees of the King Edward's Hospital Fund, and the council of the London School of Medicine for Women is assisting to raise the balance required to complete the building. Plans were prepared for erecting a home for nurses and for improving the facilities for the treatment of venereal disease (female). During the year 120 patients were treated by radium; this department is now supplied with radon free of cost by the radon centre at Middlesex Hospital. The hope is expressed that its radiotherapy equipment will shortly be supplemented by a deep x-ray apparatus. Nursing efficiency was well maintained; 27 nurses completed three years' training and gained the hospital certificate. In the medical and surgical departments the number of in-patients increased from 5,238 to 5,439. Despite the decrease in the number of out-patients from 19,847 to 18,754, which was caused partly by a revision in the scale of charges, there was additional income from this source of almost £900. This decrease has also relieved the congestion in special departments. Including casualty and maternity cases the total number of patients treated in the course of the year was 53,165. The financial position, however, continues to be grave. Although the previous year's deficit was reduced to £7,538, the committee estimates that the heavy debt already incurred by the hospital will be increased by about £8,000 during the current year. An urgent appeal is made for new annual subscribers.

Scotland.

Clark Hospital Bequests.

THE trustees of the late Mr. Edward Clark, printer in Edinburgh, have announced a list of residuary grants to hospitals and similar institutions as follows: £30,000 towards the completion and equipment of the new hospital for crippled children, at present under construction at Fairmilehead, Edinburgh; £15,000 for the endowment of an Edward Clark chair of child life and health in the University of Edinburgh; £8,000 to the Edinburgh Royal Maternity and Simpson Memorial Hospital; £5,000 to the Royal Infirmary of Edinburgh (in addition to a legacy of £10,000 already paid); £4,000 to the King Edward's Hospital Fund (London); £3,000 each to the National Hospital for the Paralysed and Epileptic, London, and to the Royal Edinburgh Hospital for Sick Children; £2,000 to Leith Hospital; and £1,000 each to the Deaconess Hospital, Edinburgh, the Edinburgh Dental Hospital, the Hospice, Edinburgh, and the Royal Edinburgh Hospital for Incurables.

Glasgow Hospital for Sick Children.

At the annual meeting of the Glasgow Royal Hospital for Sick Children on March 10th, Lord Provost Kelly, who presided, referred to the modern facilities the hospital possessed, both for treatment and for medical instruction. Dr. John F. Fergus, president of the Royal Faculty of Physicians and Surgeons, who also paid a tribute to the hospital, mentioned the valuable work it had done in the treatment of rickets, and supported the appeal that is being made for a research fund of £20,000 for further investigation of diseases of infancy and childhood.

Larbert Institution for Mental Defectives.

At the sixty-ninth annual meeting of subscribers to the Royal Scottish Institution, Larbert, the medical superintendent, Dr. Clarkson, said that the average daily number of patients—namely, 559—was the largest recorded in the history of the institution. The death rate was 0.8 per cent. of the patients under treatment; this was the lowest rate in forty years. Children's work had realized over £1,000. The villas in course of erection under the colony scheme were expected to be ready for occupation at the end of the present year. Dr. Clarkson referred to the early work of the institution, which had begun in 1860 with the opening of a small school in Edinburgh. When it was transferred to Larbert there were 9 children; to-day there were 560, and provision was being made for 250 more. The colony scheme, according to the report, consists of five large villas, each of which will accommodate 50 patients. The villas are divided into two groups—three for males and two for females—and these groups are separated by an administrative block. Helpless patients will be accommodated in another block, which will also provide room for a hospital and laboratories. Workshops will be built when funds are available.

Edinburgh Dental Hospital.

At the thirty-eighth annual meeting of the Incorporated Edinburgh Dental Hospital and School, on March 27th, under the presidency of Dr. William Guy, dean of the school, Treasurer Harvey said that only about a third of the children whose teeth were considered defective by the Edinburgh education authority took advantage of the school dental service. The Dental Hospital should be more widely recognized as providing an important health service to the community. According to the report for the year there was an income of £5,361, which included £2,217 from students' fees and £2,658 from dental appliances, etc. Over 23,000 operations were performed.

Correspondence.

THE POSSIBLE OCCURRENCE OF TULARAEMIA IN BRITAIN.

SIR,—The identification of tularaemia in Russia and Norway makes it quite likely that the infection is also present in some form in this country. The admirable review published in the Monthly Epidemiological Report of the Health Section of the League of Nations gives a full account of the Russian outbreaks, in which human beings were infected from water-rats which they were hunting for the sake of their skins. The Russian observers also found that the infection was widespread among water-rats in places where no examples of human disease had been identified. Our native water-rat is the same species (*Arvicola amphibius*) as occurs in Russia, and it would be of much interest to know whether they are also infected. If they are, transmission to man seems unlikely, for close contact with water-rats must be very exceptional; it does, however, occasionally occur—for example, in boys. It appears, too, from the last number of the *Journal of the American Medical Association* (March 8th, p. 721) that tularaemia may occur in sheep. One way and another, therefore, one suspects that the disease may only need looking for in this country to be found. Obscure cases of general illness and fever, generally with glandular enlargement and often with pustules or ulcers on the hands, etc., should be viewed with suspicion, especially in country people. The clinical course of laboratory infections was described by Professors Ledingham and Fraser in the *Quarterly Journal of Medicine* in 1924 (vol. xvii, p. 365) —I am, etc.,

London, W.C.1, March 25th. A. E. BOYCOTT.

THROAT INFECTIONS AND PUERPERAL SEPSIS.

SIR,—In his carefully planned investigation reported in the *Journal* (March 22nd, p. 533) Mr. W. W. King presents strong evidence for his view that in hospital practice "spraying" from the throat of streptococcal carriers is an important means of infection. His work, taken in conjunction with that of Armstrong[1] and others, is especially important in its implication that, this being the common method of the spread of hospital sepsis, an aseptic routine otherwise rigid must fail unless it is combined with the wearing of masks both by those attending at labour and by those in attendance during the puerperium. At the same time it is important to note that Mr. King's observations on hospital contagion do not necessarily imply, as he seems to infer, that in domestic midwifery or even

[1] *St. Bartholomew's Hospital Reports*, 1928, vol. lxii, p. 169.

in hospital practice the streptococci associated with the common epidemic throat infections constitute an important risk. As it seems to me, the value of his work extends only so far as it suggests that the streptococcus from an infected puerperal patient is signally prone to attach itself to the throat of those in attendance and in this way to be sprayed on to succeeding cases. In none of the cases quoted by him is there evidence that the throat carriers were the primary factors—that is, the originators of the first case. There is no evidence against the view that in each instance the carriers were in reality transmitting a puerperal streptococcus picked up directly or mediately from an infected hospital case. In this connexion it is important to recall that in sub-epidemic puerperal infection patients may be infected without exhibiting any fever. In Cases 2 and 3 of Mr. King's series this was actually so. From such patients streptococci virulent for other cases may conceivably reach the throat of the attendant, who would then erroneously seem to be the primary agent in a subsequent infection. Similarly Mr. King's observations may be advanced to support the view that in domestic midwifery the attendant may transmit streptococci of a like nature.

But the most important evidence against the view that haphazard epidemic throat infections are a potent factor in the community generally is much less subtle, and it argues equally strongly against the significance of endogenous infection. It is obtained from the experience of the outdoor and indoor practices of such institutions in London as the East End Maternity Hospital and Guy's Hospital. Dr. W. H. F. Oxley, in his recent paper in this *Journal* (February 15th, p. 275), which constitutes one of the most important contributions to this subject published within recent times, has shown that, where no special precautions are taken against "spraying" from the throat or to eliminate focal sepsis, the death rate from sepsis can yet be virtually abolished. A death rate from all causes of 12 in 17,525 unselected normal and abnormal cases, equivalent to 0.68 per 1,000, proves this conclusively. *The death rate in this large practice from all causes is less than half that from puerperal sepsis alone throughout the community generally.* Similarly, Mr. F. G. Gibberd (*Guy's Hospital Reports*, 1928) has shown that in Guy's Hospital during 1928 there were 1,782 successive cases, normal and abnormal, with one death from accidental haemorrhage and no mortality from sepsis.

Such data cannot be emphasized too often or too strongly, because they demonstrate that other factors are negligible compared with sound midwifery based on adequate antenatal care and proper management at labour. Further, they show that, where the hospital environment is kept free from puerperal infection by the elimination of the "emergency" or mismanaged case, which constitutes the ordinary septic case in midwifery practice, such factors as throat conveyance and endogenous infection are relatively insignificant. Conversely, hospitals which admit "emergency" cases among their clean cases assume a very grave responsibility. For some years, on the basis of their records, I have been urging that these mixed hospitals, which comprise the majority of our large central institutions, constitute a serious danger to the community, and I have given reasons for the belief that the only satisfactory solution of the problem is to segregate the "emergency" cases in special buildings, and preferably in separate hospitals provided for the purpose. Meanwhile, in our efforts, under present conditions, to battle with the extremely difficult and elusive problem of contagion, I believe Mr. King's paper is valuable in urging the importance of taking precautions against one, perhaps the chief, of the risks associated therewith, both in hospital and in domestic practice.

I would further direct attention to the statement in Mr. King's paper that an

> "analysis of the type of labour which preceded the onset of puerperal fever in the cases admitted to the Jessop Hospital in 1929 shows the surprising fact that those which had spontaneous labours had the highest rate [46.5 per cent.] of haemolytic streptococcal infections, while 'failed forceps' cases, *in which there is* usually the maximum amount of manipulation and trauma, were only infected by haemolytic streptococci in 12.5 per cent. of the cases admitted."

What the author means to imply by this statement is not clear, but it is liable to lead to an unwarranted and dangerous inference. The high rate in the spontaneous cases is natural in that they were presumably sent to hospital because of sepsis, and it is notorious that notification and segregation apply chiefly to the severest cases. In the "failed forceps" cases, on the other hand, the admission is presumably dictated primarily by the obstetric difficulty. It is the experience of all hospitals that these are peculiarly liable to suffer from severe sepsis, and the fact that in Mr. King's series only 1 in 8 so suffered is, though gratifying, hardly a reason for comparing them with cases of quite a different order.—I am, etc.,

Edinburgh, March 24th. JAMES YOUNG.

SIR,—I am much interested in the article by Mr. W. W. King on throat infections as a factor in puerperal fever, and in support of the views expressed therein I would like to quote our experience in this hospital.

Mrs. R. was confined normally on January 19th. On January 21st she developed a temperature of 102.6° F. All the members of the staff wore gloves and gowns, and all lacerations are always repaired within six to eight hours of confinement, and a cusol gauze pack is inserted in the vagina. A cervical swab was examined, and *Streptococcus pyogenes haemolyticus* was isolated.

Mrs. M. was confined on January 24th. She was in a very run-down condition, and low forceps were applied. On January 26th she developed a rise of temperature.

Mrs. B. was confined normally on January 29th, and on January 31st she developed a rise of temperature; the same day Mrs. N. was confined normally, and her temperature rose on February 11th.

We had intensified our aseptic and antiseptic precautions, and I could not understand this sequence of temperatures, and consulted with Dr. Leith Murray of Liverpool, who then suggested having the throats of the entire staff swabbed. This was done, and one nurse was found to harbour the *Strep. pyogenes haemolyticus*. She was isolated from the wards, and, as an additional precaution, it was arranged that all members of the staff should wear masks during confinements and swabbings.

The result was striking. No further case of rise of temperature occurred.—I am, etc.,

A. S. GARDEN, M.D., L.M.
Obstetrician in Charge, Southport Maternity Hospital.

March 24th.

INDIAN MEDICAL DEGREES.

SIR,—In your issue of March 29th you publish a letter from Sir Thomas Carey Evans on Indian medical degrees. In it he truly observes that the medical profession in India is the offspring of the I.M.S. Every officer, past and present, of the Service, in the hope and confident belief that its offspring will be even more illustrious than its parent, will regret the recent decision of the General Medical Council of Great Britain, and will be ready, in a parental capacity, to take on his shoulders a just share of any blame which may be attributed to the medical profession in India for that decision. It is quite another matter, however, to anticipate with the writer of the letter that the inevitable result will be disaster to "the welfare of 320 millions of our fellow subjects." The decision of the G.M.C. affects only a small percentage of the medical profession in India—for example, a few of the graduates of only four universities—who may wish to settle in practice in Great Britain or one of the Colonies, or to gain further experience by attending post-graduate courses of instruction in Great Britain. There are nine university examining bodies with affiliated medical colleges in India, and the degrees conferred by only four were recognized. The great mass of the medical profession in India is composed not of graduates, but of licentiates trained in Governmental medical schools. These are completely outside the range of vision of the General Medical Council of Great Britain. It is inconceivable that the graduates of the five unrecognized universities, and the more numerous licentiates of the medical schools, will cease or curtail their efforts in the cause of humanity because the decision of the G.M.C. has temporarily placed all graduates of Indian universities on an equal footing in the British Empire outside India.

Sir T. C. Evans rightly stresses the good work done by the medical practitioners in India in the past; in this

respect they will not be influenced by any action of the General Medical Council of Great Britain. They realize perfectly that the function of the G.M.C. is to protect the British public, and that recent action has been taken solely in the fulfilment of this function. It is unfortunate that the practically world-wide attention paid to the standard of medical education since the great war has coincided with the increasing Indianization of the medical services in India. In certain quarters this has given rise to the impression that there is a cause and effect relation. A slight acquaintance with the course of medical education will reveal the absurdity of this impression. In India I have no hesitation in asserting that the criticisms made by the G.M.C. are made without racial bias, and would have applied with equal force to pre-war conditions in the medical colleges. Racial questions naturally exist in India, and racial prejudice is not confined to Indians. It has assumed a rather more prominent position than it deserves owing to the noisy extremists of both sides. Between these two extremes is a body of level-headed individuals, both Indians and British, working together solely in the interest of India. Among them racial prejudice tends to disappear. They will realize that the General Medical Council of Great Britain in executing its duty to the general public of the Empire cannot be deflected therefrom through fear of any possible indirect political effect in India. They also can utilize the decision of the G.M.C. for the benefit of India.

Sir Norman Walker, after his recent visit, issued a very valuable report, which has deservedly received the widest attention in India. He also recommended a temporary extension of the period of recognition of the four university degrees. Speaking for Madras, I can say that every recommendation he made that could be carried out provincially was acted on. The period of recognition was again temporarily extended. The facilities for teaching now are certainly no worse, but probably better than they were under recognition. The main defect lies, therefore, in the arrangements for routine inspection of the medical colleges. The G.M.C. suggested as a remedy the establishment of a General Medical Council for India, and as a stopgap the appointment of an Educational Commissioner. The proposal for the establishment of an All-India Medical Council did not originate with the G.M.C. of Great Britain; it has been pressed by many men in India for some years, because the standard of medical education in India cannot depend on an outside body; it must be based on a strong General Medical Council in India. If the action of the G.M.C. of Great Britain assists in the realization of this aim that body will have earned the gratitude of every Indian and Britisher who has at heart the welfare of India. —I am, etc.,

F. H. G. HUTCHINSON,
Major-General I.M.S.

Bedford, March 31st.

RESEARCH IN MEDICINE.

SIR,—Although we must feel grateful for the frank opinions expressed by Sir Thomas Lewis in the *Journal* of March 15th (p. 479), those who, although engaged in clinical teaching and practice, have tried through their clinical work and observations to advance the methods of curing diseased *individuals cannot absolutely agree*: (*a*) that "the fertility of the method of observation greatly declines by a process of exhaustion"; (*b*) that the preoccupation of a practising physician is "mainly diagnostic"; (*c*) that the chief goal of the clinician is "to place a label correctly."

(*a*) The opinion that the method of observation—that is, the method of Hippocrates—has given what it had to give, and is no longer of great use, has been expressed in various periods of the history of medicine. It was expressed for the first time by a group of Greek physicians of the fourth century B.C.—the Rationalists, immediate successors of Hippocrates—later by Galen, and nearer to our days by Claude Bernard and the German physiological school of the second quarter of the nineteenth century. Not only has the Hippocratic method of observation survived these attacks, but it has developed more and more, and no other method can be applied for the most important part in *medical research—that is, for the study of the action of* therapeutic agents on the diseased individuals.

(*b*) Diagnosis is far from being the only object in medicine; in fact the word "medicine," and more precisely the Greek word *ἰατρική*, means "all that belongs to *cure*." Our main goal, therefore, is treatment, and diagnosis from a medical point of view can only be considered as part of treatment. Since the days of the first Greek physicians—the physicians of the school of Croton of the sixth century B.C.—diagnosis, prognosis, and treatment have constituted the holy trinity of medicine.

(*c*) Although we hear very often the reproach that we are mainly concerned with "placing a label on a patient," this is far from being the case. If we except certain physicians of the late eighteenth century, like Sauvages and Pinel, and also some physicians of the anatomical school of Vienna of the early nineteenth century, the object of the physician has always been to diagnose and cure *individuals* and not diseases. Diseases were introduced by the physicians of Cnidos of the fifth century B.C. as a means of classification of morbid phenomena. We need this classification for our study of the morbid phenomena. We study "diseases," we classify our research with the labels of "diseases," but we diagnose and treat individuals. It is true that the splitting of internal medicine into narrow specialties such as "diseases" of the heart, of the digestive system, of the nervous system, of the thorax, has given rise to the erroneous idea that we try to diagnose and treat "diseases"; but this division of medicine into narrow specialties has only been a temporary error in the history of medicine. It is disappearing in our day, and the contemporary internist does not run after fictitious and non-existent diseases, but, as in the days of Hippocrates, he tries to understand, to diagnose, and to treat the diseased individual as a whole.—I am, etc.,

A. P. CAWADIAS.

London, W 1, March 25th.

SIR,—I was very greatly interested in Sir Thomas Lewis's paper, and will try to emulate his frankness. I entirely agree that much that is published on clinical medicine is valueless, but I do not agree that all would be well if we were to use the "exact methods" which Sir Thomas employs. Clinical questions are too complex and have too many sides to permit their being truly expressed by such a simple formula as is required by exact science. It is often the case that one or two points which only deal with a fraction of a complicated problem are worked out carefully and painfully, leaving great gaps unexplored to be bridged over usually by arbitrary assumptions when conclusions in regard to the whole problem are drawn. The danger of too close attention to detail is always that one may be unable to see the wood for the trees. The circus theory is plausible enough if one considers excitation waves and nothing else, but as soon as an attempt is made to fit in this theory to the broad clinical features of fibrillation it becomes an absurdity. I have been acquainted with volumes full of charts and tables which were valueless, and I have known a column of printed matter in a popular journal adding a new fact to our knowledge. It established itself as a fact because it fitted in with all the other facts known on this particular subject. Mackenzie was a successful exponent of this method.

I do not blame our editors for the present state of affairs. A German journal for heart disease includes among its editors two very eminent physiologists, but nobody can suggest that its standard is higher than that of our great weekly journals. A professional editor is a specialist at his job, and above all he is an unbiased person, but the type of research worker who is strongly prejudiced in favour of a particular method, and whose suspicions are so pronounced as to permit him to trust neither the past nor the present generation of clinicians, is the last man to judge other people's work.

The present position is not satisfactory. Would a separation of the research from the consulting physician improve matters? The research physician will have all cases which interest him, and he will return them to the consulting physician as soon as they become "routine" cases; presumably the results of the special investigation will be

available. What function is left for the consulting physician? The research physician will have the most knowledge and the greatest facilities for the type of disease he is investigating; why should he not take complete charge of this type of case? It takes a long time to "arrive" scientifically; proper facilities for work are necessary, and the position of the research physician will have to be reasonably secure to be of use. How are we to recognize the *budding research genius?* We can easily imagine the level which a profession will reach when all that is left to the practising physician is the exploitation of the discoveries of the research physician for commercial gain. *Sir Thomas Lewis* was a very successful researcher while he was a consulting physician, and his subsequent career only proves that a research physician with a passion for exact methods is compelled to turn himself into a physiologist.

The problem of material remains. The provision of general wards for internal medicine is really no longer a tenable proposition, for internal medicine is ready to be divided up into four or five branches. We ought to aim at creating as large departments as possible in each branch, even if this entails the combination of several hospitals in one unit. The department must not be split up into several units, but it ought to have only one head. A department of heart disease containing three to five hundred beds in which all London cardiologists would work together under a definite direction, with proper laboratory facilities, would doubtless accomplish a great deal. *Divorce the practice of medicine from research* and it will become even more empirical than it is at present. The only way to raise the standard of our profession is to make research the sole qualification for all appointments.—I am, etc.,

Liverpool, March 21st. I. HARRIS.

RELATION BETWEEN GLANDULAR AND PULMONARY TUBERCULOSIS.

SIR,—In your issue of March 29th Dr. George Hurrell asks for statistics bearing on the relation between cervical glandular and pulmonary tuberculosis. Perhaps some figures from the post-mortem room of a children's hospital may be of interest.

Among 107 fatal cases of pulmonary and thoracic gland tuberculosis in children under 12 years of age examined post mortem in the Royal Edinburgh Hospital for Sick Children, 35 (32.7 per cent.) showed tuberculous lesions (exclusive of acute miliary tubercles) macroscopically detectable in the cervical glands. In 14 of these the supraclavicular glands, alone of the cervical group, were affected, and they were in close relation to, and were probably infected from, grossly enlarged glands in the thorax. In most of these 14 cases the enlargement of the supraclavicular glands was sufficiently great to be obvious on *clinical examination.* In the other 21 cases the upper cervical glands were affected alone or in combination with the inferior group. In several cases evidence of tuberculous infection was found only in the tonsillar gland on one or both sides. In 2 of the 21 cases there was advanced caseation with considerable enlargement. In the other 19 the enlargement was so slight that it was unlikely that "gross glandular disease" would have been diagnosed during life: the glands showed only small caseous foci, which, to judge by appearances, were of much more recent origin than the disease in the chest. As 18 of these 21 cases had gross open tuberculosis in the lungs, it seems probable that the efforal gland infection was secondary to the pulextremely difficurred by way of the tonsils, from in- f believe Mr. King ng there. Only one case had been tance of taking precious cervical lymphadenitis. of the risks associated gross visible swellings" (Dr. domestic practice. were present in about 15 per I would further direct id not indicate anything like Mr. King's paper that an c d involvement. At the alysis of the type of labour w clearly that in only al fever in the cases admitte ination warrant the s the surprising fact that th infection may have the highest rate [46.5 per ce tions, while 'failed forceps' was this the most maximum amount of manipu cts. d by haemolytic streptococci i

Among a further series of 11 fatal cases in which the cervical glands were grossly caseous, only one showed any tuberculous lesions (apart from acute miliary tubercles) within the thorax. These took the form of small scattered subacute foci in the lungs (which probably could not have been detected during life), without involvement of thoracic glands.—I am, etc.,

Edinburgh, March 30th. A. R. MACGREGOR, *Pathologist, Royal Edinburgh Hospital for Sick Children.*

SIR,—Dr. George Hurrell suggests that statistics on this important point would prove interesting. In the *British Medical Journal* of February 25th, 1922, Mr. W. J. Fanning and I published some particulars in regard to 3,220 patients admitted to Kelling Sanatorium between the years 1905 and 1919. Of that number 4 per cent. had previously suffered from glandular abscesses. This number agrees closely with Dr. Hurrell's findings as published in his letter to your *Journal* of March 29th (p. 618). But I am bound to add that in our communication I went on to say that "our strong impression is that this understates the frequency of this association." At the time I had in my mind more than one case of acute pulmonary tuberculosis which had immediately followed treatment of glandular enlargement by operation or by tuberculin, and which was too severe for removal to a sanatorium.—I am, etc.,

Norwich, March 31st. F. W. BURTON-FANNING.

DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS.

SIR,—Permit me to make a few comments on the matter at issue between Drs. W. Arnott Dickson and E. Weatherhead—namely, the subcutaneous tuberculin test. Dr. Weatherhead (March 15th, p. 516) advocates this as "the only tuberculin test which is now commonly held to have any real diagnostic value." I am not sure that this view is commonly held; but I certainly hold it. Dr. Dickson (March 22nd, p. 567) does not avail himself of this test at all, because of the supposed "risk of a dangerous focal reaction." But Dr. Weatherhead's statement, as I understand it, was only to the effect that giving test doses to patients whose mouth temperature runs as high as 99.2° F. involves some risk. I do not give test doses to patients when their temperature on the day for injection, or the preceding day, has exceeded 99°; and I have found no dangerous focal reactions resulting.

I have used the subcutaneous tuberculin test as the deciding factor in diagnosis in 764 doubtful cases, spread fairly evenly over the time from January, 1913, to the present. These included cases of haemoptysis, pleurisy with non-purulent effusion, fibrosis, etc., in which the sputum, if any, did not contain tubercle bacilli. My method is to give old tuberculin human (T) 0.0002 c.cm. for the first dose, and, if no reaction results, to double the dose each time up to six doses, before pronouncing the result negative. In 454 of the 764 cases (almost 60 per cent.) a positive reaction was obtained. In these cases the patient was informed that the test showed that it was worth while having a course of treatment extending over at least six months. The great bulk of those who took this advice got quite well. In 34 of these 454 cases tubercle bacilli were subsequently found in the sputum. The 310 patients in whose cases the test gave a negative result were assured that they were not suffering from tuberculosis. It is a great comfort to the patient and his friends when one can give such an assurance: the elimination of 40 per cent. of doubtful *afebrile* cases is also exceedingly useful from an administrative point of view.

It is very important to know whether such an assurance is well founded. In 6 of the 310 negative cases tubercle bacilli have subsequently been found in the sputum: a reasonable inference is that a negative result does not indicate that the patient is immune to tuberculosis for life, but only that he was not suffering from tuberculosis at the time of the test. In three cases, however, the interval between the last of the negative test doses and the finding of tubercle bacilli in the sputum was less than six months.

Even if we regard these three cases as instances of failure of the test for practical purposes, the percentage of failures is rather less than 1 per cent.; which is very small compared with the percentage of failures of other specific tests which are highly thought of, such as the Wassermann test for syphilitic conditions. If Dr. Dickson would use the subcutaneous tuberculin test, I believe he would find, as I have, that not all cases of pleurisy with non-purulent effusion are tuberculous.—I am, etc.,

Belfast, March 24th. JOHN R. GILLESPIE.

SIR,—I should like to thank Dr. Arnott Dickson, whose lecture on the diagnosis and treatment of pulmonary tuberculosis appeared in your issue of March 1st, for his masterly exposition of his subject, which many other busy practitioners like myself must be grateful for. There are, however, two points barely touched upon which, if enlarged upon by the lecturer, would, I imagine, be of great interest.

The first is wrapped up in his decision, "I shall say nothing about tuberculin treatment, which is not being used to any extent in pulmonary tuberculosis." I would like to ask, "Why not?" As a general practitioner, fated to meet with every phase of pulmonary tuberculosis from the suspect to the last-stage consumptive, and conscious of the responsibility that attaches to a medical practitioner in a British colony on foreign soil, I have not been able to keep my head so resolutely turned away from the promise held out by some men of high standing—namely, M. Spahlinger of Geneva, Dr. Camac Wilkinson of London, and Dr. Crofton of Dublin—that salvation may be found in an appreciable number of cases from the administration of tuberculin, as one gathers from Dr. Dickson's lecture the majority of the profession have apparently been able to do. There is a world war being waged against tuberculosis, but it would seem that, in spite of the positive evidence of the value of tuberculin treatment in certain cases, such as those above referred to, there are many "conscientious objectors" to its use among general practitioners. I would therefore ask, as a general practitioner, if Dr. Dickson cannot give a less non-committal verdict than is tacitly conveyed in the words quoted from his lecture, by answering the direct question, "Why not?"

The second point on which a little more practical detail would assuredly be appreciated, again on the question of treatment, is dismissed with the bare mention, "the enormously important psychical factor." Presumably the psychical factor is most systematically exploited in those institutions in which occupational treatment is routine. It would help the general practitioner considerably to know what incentive to transcend the bacillary stigma the author advocates for those patients who for one reason or another are unable to embark on institutional treatment.—I am, etc.,

Nice, March 12th. F. A. HOBT.

PREDESTINATION IN DISEASE.

SIR,—I have read with interest Dr. Langdon Brown's lecture entitled "Predestination in disease" (*Journal*, March 22nd, p. 525). With regard to his remarks on pernicious anaemia and subacute combined degeneration, however, there are some points to which many will take exception.

In the first place, Castle's work is misquoted. To state that "he concluded that this acid digest stimulated the patient's liver to produce something which prevented the breakdown of red corpuscles" is incorrect, as reference to his published work will show.[1] Secondly, the conception of subacute combined degeneration as of "toxic" origin has yet to be proved. Like pernicious anaemia,[2] it is much more likely to be a deficiency disease.[3] Dr. Langdon Brown states: "Once degeneration of the cord has occurred, treatment by liver is, of course, unable to restore it, but in the earlier stages, when there are only toxic symptoms and before structural changes have occurred, this remedy is of decided benefit." Such a statement gives an erroneous impression. Actually the duration of the disease before treatment was commenced in our seventeen improved cases varied from three months to two years, the average period being 13.7 months; ten of the patients were bed-ridden, while the remaining seven had such great difficulty in walking that they were confined to the house. These facts, in association with the definite physical signs analysed elsewhere, scarcely suggest that only "toxic symptoms" and no "structural changes" had occurred.

Thirdly, upon what grounds does Dr. Langdon Brown make the statement that "most neurologists would not accept the diagnosis in some of the cases reported there [Newcastle] by Ungley and Suzman"? The evidence upon which the diagnosis of these cases was based has been fully analysed, and cannot be repeated here. It is enough to say that it has been accepted by foremost neurologists and published in *Brain*.[3] Lastly, in view of Castle's findings and of the fact that HCl has apparently no effect on either blood or cord symptoms, and does not affect the response to liver,[3 4] it is difficult to see how its administration to relatives of cases of pernicious anaemia is going to be of any help in preventing the disease. Even digestion with HCl and commercial pepsin seems incapable of forming the specific factor from meat protein, although normal gastric juice has this property, as Castle[4] has shown.—I am, etc.,

NON-ABSORBENT COTTON-WOOL COCAINIZATION.

SIR,—In my remarks on the anaesthetization of the larynx with a 20 per cent. solution of cocaine, at the recent meeting of the Section of Laryngology, I insisted on a detail which is not mentioned in the report of the proceedings (March 29th, p. 593). Though in a general way the difference between absorbent and non-absorbent cotton-wool seems very trivial, it is one of great importance when strong solutions of dangerous drugs are employed. I urge most strongly that the swabs used for applying solutions of cocaine or its congeners should be made of non-absorbent—non-defatted—cotton-wool instead of absorbent. It is easy to realize that we want a solution on the surface of the swab, where it touches the mucous membrane, and not in the interstices, where it is not required, and from which the excess of the solution can be squeezed out into the lumen of the cavity. This is from one point of view mere waste, and from another a source of dangerous intoxication. The simplest experiment with the two kinds of cotton-wool makes this quite evident.—I am, etc.,

London, W., April 1st. JAMES DUNDAS-GRANT.

PERCAIN AS A SURFACE ANAESTHETIC.

SIR,—Messrs. Norman C. Lake and C. Jennings Marshall in their most interesting paper, "Clinical experiences with percain" (March 15th, p. 488), refer only briefly and with little enthusiasm to its effect as a surface anaesthetic.

Apart from stating that in a dilution of 1 in 1,500 for the urethral mucosa they have not found percain as effective as the cocaine chloretone combination (concentration not stated), the authors do not touch the question of its use as a surface anaesthetic. In my opinion this constitutes one of its chief merits, and the only one from the rhino-laryngologist's point of view. I am aware that extreme caution is necessary in introducing toxic substances into the urethra, but would suggest that the great dilution (1 in 1,500) of percain used hardly constitutes a fair test. I understand that a 2 to 4 per cent. novocain solution is often employed for this purpose. Assuming that percain is twenty times as toxic as novocain, the corresponding solutions would be 1 in 1,000 to 1 in 700, which is the strength recommended by the makers. Mr. J. Llewellyn Davies informs me that in his experience the 1 in 1,000 percain solution gives sufficient anaesthesia of the urethra and bladder to enable him to apply diathermy to papillomata of the bladder through an operating cystoscope.

Through the courtesy of the Clayton Aniline Company I was supplied with a quantity of percain about three

[4] Myers, G. H., and Richardson, W.: *Journ. Amer. Med. Assoc.*, 1926, 87, 923.

months ago in order to test its efficiency when applied to the mucous membrane, particularly that of the nose. I had 1 per cent. and 2 per cent. solutions of percain made up according to the directions supplied; to each 50 c.cm. of the solution was added 1/2 c.cm. adrenaline (1 in 1,000). These solutions I have used in both my hospital and private practice in place of the 5 per cent. and 10 per cent. cocaine hydrochloride solutions. I applied the percain by means of ribbon gauze or cotton-wool tampons, which were just wet but not dripping. In all cases I have achieved satisfactory anaesthesia. The operations have included partial resections of turbinals, removal of polypi, ethmoidal curettages, and intranasal drainage of the maxillary antrum. The patient in each case assured me that he felt no pain, but occasionally was aware that I was touching something inside his nose. In the more extensive intranasal procedures I applied a tampon of 10 per cent. percain to the mucous membrane in the immediate vicinity of the spheno-palatine ganglion for five minutes. Clinically it is not easy to judge depth of surface anaesthesia, but my impression is that percain is adequate. It seems to act in less time than does cocaine, and to give more prolonged anaesthesia.

Three of my patients complained of faintness immediately after the percain was applied, but, curiously enough, all three were adults. This faintness was never accompanied by excessive pallor, slowness of pulse, or shallow breathing. After giving a stimulant drink I was able to proceed without interruption in each case. The time that elapsed between the application of the percain and the faintness was too short for a sufficient quantity of this drug to be absorbed. The psychological factor in these cases I believe might with fairness be held responsible. I have had no untoward effects in children. The makers suggest that mucous membrane is not permeable to this drug, although profoundly affected by it; and that percain does not reach the general circulation when applied to the membrane. The quantity of percain used in rhino-laryngology is not likely to reach the toxic threshold (0.01 gram per kilogram body weight), and if the above claim is correct it would provide an added safeguard.

If one may be permitted to draw conclusions after so short a trial I would say:

1. That percain procures surface anaesthesia in mucous membrane; and that of all the drugs for which a similar claim has been made, apart from cocaine, it is the only one that does this satisfactorily.

2. That with certain refinements of technique—possibly the use of stronger concentrations—it is not unlikely that percain will oust cocaine from rhino-laryngological practice.

3. That caution is to be exercised in using it, in view of its admitted toxicity (twice that of cocaine), although in rhino-laryngology the quantities used are not likely to exceed 20 per cent. of the stated toxic dose.

It is not my intention to minimize the advantages that percain employed in local infiltration has over other local anaesthetics, but to emphasize what I believe to be of much greater and far-reaching importance—namely, its value as an effective cocaine substitute.—I am, etc.,

London, W.1, March 18th. O. POPPER.

MARGARET MACDOWALL.

SIR,—I desire to join Sir Maurice Craig in his appreciation of the late Miss Margaret Macdowall. I have known her from the time she started her school at Ealing, and it has been my privilege to pay regular visits to her since she moved to Burgess Hill. She was not only the recognized leader amongst those who have devoted their lives to the practical training of mental defectives, but she trained a band of disciples to follow in her footsteps, and many of the leading teachers in this country at the present day owe their enthusiasm and knowledge to her personality and teaching. Her methods were primarily based upon the principles formulated many years ago by Séguin, and introduced into this country by the late Dr. Shuttleworth, of whom she was almost a lifelong friend. She was, however, no slavish adherent to any system, but devised many valuable practical methods of her own. The keynote of her success was her close study and intimate knowledge of the special aptitudes and disabilities of each pupil committed to her charge, and her unremitting and patient attention to their individual needs. I have never met a teacher who knew more about her pupils than did Miss Macdowall, nor one who was capable of bringing more patient and sympathetic understanding to bear in developing them to the utmost limit of their capabilities. All that she did was done wholeheartedly, unselfishly, and unobtrusively. There will be many who will miss her kindly sympathy, and her death is a serious loss to the cause to which she had devoted her life.

She was the author of a small but most useful practical guide to training methods. This has now been out of print for some time, and I am very glad to hear that the publication of another edition is contemplated. It would form a very fitting memorial of her work.—I am, etc.,

London, W., March 25th. A. F. TREDGOLD.

"A SCOT IN WALES, 1600-1620."

SIR,—In reference to Miss Hall's account of Alexander Reid (March 22nd, p. 558) we should not forget the active part he took in the question as to the possibility of excising the spleen, and his own successful operation on a dog, probably the first excision in this country—which settled the matter.

Like his fellow countryman, Peter Lowe, he had studied everywhere, and in London he rose to be the chief teacher of surgery at the time of Woodall and Cooke. His lectures and treatises seem to me a great advance on most of his predecessors.—I am, etc.,

Clifton, March 25th. G. PARKER.

HENRY HICKMAN MEMORIAL.

SIR,—The Henry Hill Hickman Memorial Committee has to report that the total sum received amounts to £256 10s. 6d., and that the appeal is now closed.

Hickman's family grave and tombstone have been restored and renewed, and a tablet engraved by Mr. Eric Gill is to be unveiled in Bromfield Parish Church, Ludlow, by Sir StClair Thomson, M.D., F.R.C.S., late President of the Royal Society of Medicine, on April 5th next, at 2.45 p.m. This will be followed by a dedication by the Right Rev. the Lord Bishop of Hereford.

The balance of this fund will be devoted to establishing and endowing a medal for research and original work of merit in connexion with anaesthesia. Further particulars, including the names of the trustees appointed, will be published later.

The committee desires to express its cordial thanks to the numerous colleges, faculties, learned societies, and individuals who have so readily supported this appeal.—We are, etc.,

DAWSON OF PENN.
STCLAIR THOMSON.

Obituary.

DR. JOHN DIXON died, on March 31st, at his home in Jamaica Road, Bermondsey, at the great age of 98. He came of a long-lived Yorkshire family, and, so far from being bedridden, was able to attend, with obvious relish, the Buckston Browne annual dinner of Fellows and Members of the Royal College of Surgeons of England last November. He was born at Hessle, in the West Riding, and after apprenticeship to a country surgeon entered Guy's Hospital in 1851, graduating M.D. at St. Andrews University in 1854, in which year he also obtained the diplomas of M.R.C.S.Eng. and L.S.A. He was admitted a licentiate of the Royal College of Physicians in 1861. For many years he had a large practice in South London, and combined with this the work of medical officer of health for Bermondsey, surgeon to the Surrey Dispensary, Poor Law district medical officer, public vaccinator, and certifying factory surgeon. He was also honorary surgeon to the 10th Surrey Volunteers from 1859 to 1869, was appointed a Justice of the Peace for the County of London in 1901, and became Master of the Loriners' Company in 1911. Dr. Dixon is believed to have been the oldest Freemason in the country, if not in the world, having been initiated in the Mount Lebanon Lodge as long ago as January, 1856. He was installed Master in 1860, the centenary year of that Lodge, and again half a century later. During his seventy-four years of active connexion with the craft Dr. Dixon held many high offices. Entering the Royal Arch Degree in 1857, he was a founder of the Mount Lebanon and Caveac Chapters, Past Assistant Grand Director of Ceremonies of England, and Past Grand Standard Bearer of England. He was also a founder and first Master of the Southwark Mark Lodge, and was installed again in 1926, when he was made Past Grand Senior Overseer of England. John Dixon was born in the year that the British Medical Association was founded. He joined it in 1874 and remained a member until his retirement from active practice. Up to his last illness he was a heavy cigar smoker and enjoyed dining out. He always spoke of Bermondsey as a very healthy district, and boasted that he had never been laid up by ill health.

DR. PEVERELL SMYTHE HICHENS, who died at Guernsey on March 29th, at the age of 59, received his medical education at St. Thomas's Hospital, and graduated M.B., B.Ch. Oxon., in 1895, proceeding M.D. in 1903. He obtained the diplomas M.R.C.S., L.R.C.P., in 1896, became M.R.C.P. in 1899, and was elected F.R.C.P. in 1911. After holding the posts of house-physician to St. Thomas's Hospital and assistant resident medical officer at the Hospital for Consumption and Diseases of the Chest, Brompton, he practised at Northampton and was appointed physician and later consulting physician to the Northampton General Hospital; he was also consulting physician to the Northants Sanatorium. He contributed to our columns in 1903 an article on the sanatorium treatment of pulmonary tuberculosis, with special reference to the Nordrach methods, and subsequently published reports of clinical cases. He held a commission as lieutenant-colonel R.A.M.C.T.A.; during the war he served in France at the casualty clearing station of the 1st South Midland Division, and subsequently at the 35th General Hospital. He removed to Guernsey about six years ago, and was a member of the Guernsey and Alderney Division of the British Medical Association.

The following well-known foreign medical men have *recently died*: *Dr. SCORITCHENKO-AMBODIE*, the oldest professor in the academy of military medicine at Leningrad; *Dr. AMILCARE BIETTI*, director of the ophthalmological clinic at *Bologna*, aged 60; and *Dr. DOMINGO CABRED*, a psychiatrist of Buenos Aires.

The Services.

NAVAL MEDICAL COMPASSIONATE FUND.

A MEETING of the subscribers of the Naval Medical Compassionate Fund will be held at 3.30 p.m. on April 24th at the Medical Department of the Navy, Queen Anne's Chambers, Tothill Street, Westminster, S.W.1, to elect six directors of the Fund.

DEATHS IN THE SERVICES.

Fleet Surgeon William Redmond, R.N. (ret.), died at Vancouver, on February 15th, at the great age of 80. He was educated at Trinity College, Dublin, and at the Richmond Hospital in that city, and took the L.R.C.S.Ed. in 1860, and later the L.R.C.P.Lond., after which he entered the Navy. He attained the rank of fleet surgeon on August 8th, 1881, nearly half a century ago.

Surgeon Captain Oswald Rees, R.N. (ret.), died at Abbotsbury, Dorset, on February 12th. He was educated at Glasgow, where he graduated as M.B. and C.M. in 1889, and as M.D. in 1894. After filling the posts of resident assistant of Glasgow Western Infirmary, and of senior resident officer of Macclesfield General Infirmary, he entered the Navy. He attained the rank of surgeon commander on May 15th, 1909, and retired, with an honorary step as surgeon captain, on April 12th, 1920. He then went into practice at Abbotsbury, where he was medical officer and public vaccinator of the Abbotsbury district of Weymouth Union and of the Long Bredy district of Dorchester Union. In 1923 he became a member of the county council for the Abbotsbury Division and a member of the general purposes health and housing committees. He also rendered great service on the Dorsetshire Insurance Committee, but, owing to ill health, had to resign last year. From 1925 to 1926 he was chairman of the West Dorset Division of the British Medical Association. In 1897 he had served as surgeon of H.M.S. *Jackdaw* on the River Niger, and received the Sir Gilbert Blane medal for his journal; in 1901–4 he was staff surgeon at Simon-town Royal Naval Hospital, and received the South African medal for his services in the war; in 1905–7 he was secretary of the Admiralty Committee on Deep Diving, and received the thanks of the Admiralty for experimental work carried out in connexion with this committee. In 1908–9 he served as staff surgeon of H.M.S. *Fox*, employed in blockading the Warsangli coast of Somaliland; and in 1909–10 in suppression of traffic in firearms across the Persian Gulf, during which time four dhows were captured; in April and May, 1909, he formed one of the party landed for the occupation of Bushire and the protection of the Residency; the officers and men so employed received the thanks of the Foreign Office for the occupation of Bushire, and of the Colonial Office for service in Somaliland.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Army and Air Force Annual Bill and the Coal Mines Bill have been before the House of Commons this week. On March 30th the House discussed maternity and child welfare, and the status of pharmacists under the Poor Law, besides other subjects. On Friday the Unemployment Insurance Bill was down for second reading.

In the House of Lords the Workmen's Compensation (Silicosis) Bill was due to be read a second time on April 3rd.

The Budget will be opened in the House of Commons on April 14th, and the House will adjourn for Easter from April 17th to April 29th.

It is understood that when the report stage of the Mental Treatment Bill is taken in the House of Commons Conservative medical members of Parliament will concentrate on an attempt to remove the prohibition against unpaid members of the Board of Control and to secure the provision of medical assessors for applications respecting actions against medical men under the Lunacy Acts.

The text of the Housing (No. 2) Bill was issued this week. This is Mr. Greenwood's bill to accelerate slum clearance and the reconditioning of districts which are lapsing into slums. It does not apply to Scotland, which is to be dealt with by a separate bill. Another bill is promised on town-planning.

Conferring this week with Labour members of Parliament who sit in the Committee on the Road Traffic Bill, Mr. Morrison indicated that the support for the proposed insurance contribution in aid of hospitals in which motor casualties are treated was so great that he was constrained to accept this amendment and to strengthen it.

On March 31st Dr. Vernon Davies presented a bill to amend the Poor Law Officers Superannuation Act, 1896, and it was read a first time.

Mental Treatment Bill.

COMMITTEE STAGE CONTINUED.

A warning that the committee stage of the Mental Treatment Bill ought to close on April 1st was given, on March 27th, by Mr. GREENWOOD, who told the committee that if progress was further delayed he would have difficulty in finding Parliamentary time for the concluding stages of the bill. During the same sitting Mr. Greenwood gave notice of an important amendment dealing with the civil and criminal liability of medical men. This will be moved during the report stage.

The committee commenced its sitting on March 27th by approving Clause 15 of the bill, dealing with the power of the Board of Control to make rules, and with the laying of these rules before Parliament. Mr. Greenwood gave an assurance that these rules would be placed in the hands of local authorities before they were *put into operation*.

Clause 16 of the bill runs as follows:

(1) The principal Act and Section sixty-three of the Mental Deficiency Act, 1913, shall have effect and, subject as provided in this Section, be deemed always to have had effect, as if the following Section were substituted for Section three hundred and thirty of the principal Act:

> "(1) Where a person has presented a petition for a reception order, or signed or carried out, or done any act with a view to signing or carrying out, an order purporting to be a reception order or any report or certificate purporting to be a report or certificate under this Act, or has done anything in pursuance of this Act, he shall not be liable to any civil or criminal proceedings whether on the ground of want of jurisdiction or on any other ground unless he has acted in bad faith or without reasonable care.
>
> "(2) If any proceedings are taken against any person for presenting any such petition or for signing or carrying out, or doing any act with a view to signing or carrying out, any such order, report, or certificate, as mentioned in Subsection (1) of this section or doing anything in pursuance of this Act, such proceedings shall, on application to the High Court, be stayed on such terms as to costs and otherwise as the Court may think fit, unless the Court is satisfied that there is substantial ground for alleging that such act was done in bad faith or without reasonable care."

(2) This Section shall not affect any civil or criminal proceeding pending at the commencement of this Act.

In moving to add "application or recommendation" after "any report," Mr. Greenwood said these words would cover the new procedure under the bi[illegible] in the case of voluntary boarders and [illegible] in respect of minors. The committee agreed to the amendment.

Dr. MORRIS-JONES moved to substitute for the words "without reasonable care" the words "negligently and without reasonable and probable cause. Provided that in the case of a trial with a jury the question of reasonable or probable cause shall be determined by the judge."

Mr. GREENWOOD said three amendments were before the committee with the same object of giving fair protection to the medical profession against unfair and vexatious actions. It was important this should be done. The Royal Commission had considered the matter at great length, and two distinguished lawyers, Lord Macmillan and Sir William Jowett, had drafted the wording which was incorporated in the bill. Mr. Greenwood added that subsequently he saw representatives of the British Medical Association. He could not agree to their claim for absolute privilege, but had said he was prepared to go a little further if that could be done properly. He thought Dr. Morris-Jones's amendment did not achieve its object. Nor could he accept an amendment in the names of Sir Boyd Merriman and Dr. Fremantle. This amendment proposed to omit the section of Clause 16 dealing with the power of the High Court to stay proceedings, in order to substitute the words:

> "(*a*) The person taking such proceedings shall apply to the High Court for leave to proceed therein after service of the writ and before taking any further step in the said proceedings. *Fourteen days'* notice of such application shall be given to every other party to the said proceedings. Upon hearing such application the Court shall refuse leave to proceed and shall stay the said proceedings on such terms as to costs and otherwise as the Court thinks fit, unless the Court is satisfied that there is substantial ground for alleging that such act was done in bad faith or without reasonable care;
>
> "(*b*) Where the person taking such proceedings shall have taken any further step therein after service of the writ and without having obtained leave to appeal upon an application for leave to proceed as required by subparagraph (*a*) of this Subsection or where the said person has taken no further step therein after service of the writ, and failed to make such application for leave to proceed within a reasonable time from the date of service of the writ, the High Court shall, on the application of any other party to the said proceedings, stay the said proceedings on such terms as to costs and otherwise as the Court thinks fit."

Mr. Greenwood said he would prefer a later amendment. (See proposed addition at end of subsection commencing: "(3) For the purpose of determining," etc.) He added that he had prepared a new form of words giving the sense of this last amendment, and was prepared to move it as an alternative.

Dr. MORRIS-JONES then withdrew his amendment, and Dr. FREMANTLE moved the amendment set out above, commencing "(*a*) The person taking such proceedings . . ." He said the amendment was supported by Sir Boyd Merriman, who wished it to be read in conjunction with a subsequent amendment to add, at the end of the subsection, the words:

> "(3) For the purpose of determining any question under the preceding subsection the Court may, at its discretion, sit with one or more assessors nominated by the Lord Chancellor from a panel of names recommended by the President of the British Medical Association."

Dr. Fremantle went on to say that under Section 330 of the Lunacy Act a medical man who signed a certificate might be challenged by a patient, or relative, or other interested person, but it was provided that "he shall not be liable to any civil or any criminal proceedings if he has acted in good faith, and with reasonable care." The difficulty had been the interpretation of the law. In the Hume-Spry case Lord Justice Banks held, as the result of reading the section, that "if there was any scintilla of evidence to go before the jury in respect of the claim, then the claim could not be withheld from the jury." That meant that the safeguard in the section was no safeguard. It was impossible to say that there would not be some scintilla of evidence enabling the case to go before a jury. On the other hand, a case in December of last year was decided against the doctors by the Master in Chambers, not on the ground that he was not satisfied of their good faith, but that he was not satisfied that they had shown evidence of reasonable care. The judgement was reversed on appeal, and the remarks of Lord Justice Scrutton were very much to the point. He emphasized the importance of protecting those who, at the invitation of Parliament, fulfil a duty in the interests of the community as well as of the patient. They had had a series of cases in recent years showing the risks to which doctors were exposed by actions alleging that they had certified improperly, either dishonestly or without due care. It was common knowledge that the result of these cases had been that many doctors would not certify at all. They would not run the risk of undertaking the duty Parliament put upon them. The Royal Commission said the medical man was not compelled to certify, that he did it as a public service, and that if he had to run the risk of being mulcted in damages, even up to £30,000, it was not worth while, for the sake of the few guineas or few shillings of the certification fee, to run the risk and subject himself to the worry. The Royal Commission was concerned at the growing reluctance of practitioners to grant certificates, and was satisfied that further protection should be given them, otherwise a breakdown of the system was inevitable. That, Dr. Fremantle said, was the position confronting the committee. The Minister had said he could not grant the original claim of the

British Medical Association for complete privilege. The Association, recognizing that, had put itself in the hands of Mr. Stuart Bevan, K.C., and the result was the amendment which Dr. Fremantle had moved. That amendment detailed procedure to be adopted before anyone could prosecute a medical man or bring a case against him on the grounds that he had not acted in good faith or with reasonable care. The person bringing the charge had, first of all, to prove a prima facie case. That person had to go to the High Court and make out his case, and the Court had to say whether or not it was a prima facie case.

The CHAIRMAN OF THE COMMITTEE (Mr. Cecil Wilson) here intervened to point out that Mr. Greenwood had circulated a manuscript amendment of Subsection 2 of Section 1 of Clause 16 (the subsection commencing "If any proceedings are taken against any person for presenting any such petition") in order to substitute a new subsection, which would run:

"(2) No proceedings, civil or criminal, shall be brought against any person in any Court in respect of any such matter as is mentioned in the last preceding subsection, without the leave of the High Court, and leave shall not be given unless the Court is satisfied that there is substantial ground for the contention that the person against whom it is sought to bring the proceedings has acted in bad faith or without reasonable care.

"(3) Notice of any application under the last preceding subsection shall be given to the person against whom it is sought to bring the proceedings, and that person shall be entitled to be heard against the application.

"(4) Where on an application under this section, leave is given to bring any proceedings and the proceedings are commenced within four weeks after the date on which leave was so given, the proceedings shall for the purpose of the Public Authorities Protection Act, 1893, be deemed to have been commenced on the date on which notice of the application was given to the person against whom the proceedings are to be brought."

The Chairman said this amendment would have to be moved in the report stage.

Dr. FREMANTLE proceeded to deal with the further amendment which he proposed to add at the end of the subsection. He said it was to enable the Court, at its discretion, to sit with an assessor, either a medical man or a lawyer, who would be nominated by the Lord Chancellor from a panel recommended by the President of the British Medical Association. That would give greater confidence to the medical profession. There was nothing mandatory about the amendment. The Court "may, at its discretion, sit with one or more assessors." The assessors were not to be hole-and-corner medical men.

Mr. GREENWOOD remarked that he believed it to be part of Dr. Fremantle's case that there was a precedent in the case of nautical assessors. He denied the analogy. The request now was for medical assessors to deal with a case between a layman and a professional person. They were to be recommended by the British Medical Association, and the appointment of lawyers would be still more offensive to the Court than the appointment of medical assessors. The point at issue in the cases would be whether a doctor had acted in good faith and with reasonable care. The Lord Chancellor held that the procedure proposed by Dr. Fremantle ought not to be adopted.

Dr. VERNON DAVIES said the sole object of Dr. Fremantle's amendment was to aid the administration of the Act by giving better protection to doctors, whose constant and willing co-operation was needed. Cases occurred where insane persons could talk rationally for two hours at a time, and five or ten years later a clever barrister could easily make a prima facie claim for such a case, and would secure leave to bring an action. The doctor would then have to pay for his own defence.

Mr. ALFRED SMITH: The British Medical Association would pay.

Dr. DAVIES: No, they are not able to pay. He maintained that a judge in chambers or in the High Court might not be able to give certain evidence its proper medical significance, and would be aided if he could ask the advice of an independent medical man at his side. There was an analogy in the administration of the Workmen's Compensation Act, where the county court judge had a medical assessor sitting with him. The legal mind and the medical mind were trained differently, and it was difficult for them to understand each other's view.

Mr. SOMERVILLE HASTINGS said there was great value in having a medical assessor sitting with the judge in many difficult medico-legal cases. On the other hand, it would be a mistake to limit the assessors to a panel of names recommended by the President of the British Medical Association, or to bring that Association into the matter at all. That Association represented the most reactionary and commercial section of the profession. Discretion should be left to the Lord Chancellor or to the President of the Royal College of Physicians.

Miss LAWRENCE asked the committee to vote against the proposed nomination of assessors on the question whether there was a case to put before a jury. To those who thought the Government proposed to give too much protection to doctors she said there was danger of frivolous and even insane complaints. The Government was accepting in substance the first amendment proposed by Dr. Fremantle, but could not accept his words for minor drafting reasons. She asked Dr. Fremantle to withdraw his amendment, leaving the Government amendment to come up on report, when members would be free to propose further improvements in it.

Dr. FREMANTLE agreed to this suggestion. Dr. Fremantle's amendment was then withdrawn, and he moved his further amendment authorizing the employment of assessors. He agreed that there was something in Mr. Hastings's contention that recommendation by the President of the British Medical Association was open to question. The Association was the most representative body of practitioners, but the authoritative body representing the profession was the General Medical Council, while in the scientific world the representative bodies were the Royal College of Physicians and the Royal College of Surgeons. It might be well to have recommendations from several bodies.

Dr. VERNON DAVIES moved to omit from the amendment the words providing that the recommendations should be by the President of the British Medical Association.

The committee agreed to this, but rejected the main proposal for the appointment of assessors by 18 to 9.

On the question that Clause 16 stand part of the bill, Mr. KINLEY said the whole desire of the discussion had been to safeguard the medical man. The patient ought to be protected by a refusal to give any indemnity to the medical man.

Dr. MORRIS-JONES said there was no act which a medical man regarded more seriously than that of certifying a patient as insane. Medical men asked for the protection of the conscientious practitioner.

Dr. DAVIES supported this, and the clause was added to the bill.

Clause 17, dealing with the issue of emergency orders for rate-aided persons, was added to the bill. Mr. GREENWOOD explained that under the present law a rate-aided patient, in an emergency, had to be removed to the workhouse, whereas a private patient could be taken to a mental hospital. The clause would allow a rate-aided patient to go direct to a mental hospital.

The clause was added to the bill, and after an appeal by the Minister for the committee to finish its work at the next sitting the debate was adjourned.

The committee continued its discussion of the bill on April 1st.

On Clause 18, dealing with rate-aided patients, Mr. GREENWOOD reminded the committee that the main provisions of the Act would not come into force till January 1st, 1931. He proposed that Clauses 18 and 19 should come into force immediately on the passing of the Act. Clauses 18 and 19 were then added to the bill with this amendment and other minor changes.

On Clause 20 the committee accepted an amendment from Miss LAWRENCE to substitute "voluntary patient" for "voluntary boarder" in any local Act. Dr. MORRIS-JONES proposed to omit the word "lunatic" from the Lunacy Acts, with a view to substituting "mental patient" or "person of unsound mind." The clause proposes to substitute, in these Acts, "mental hospital" for "asylum" and "rate-aided" for "pauper." Mr. GREENWOOD said that to get rid of "lunatic" would be more difficult. If the committee felt strongly about it he would propose to add that the word "lunatic," except in the context "criminal lunatic" or in regard to insane persons escaped outside England, should cease to be used under the Lunacy Acts or in Ministry of Health administration, "person of unsound mind" being substituted in regard to any person of, or alleged to be of, unsound mind. He pointed out that "mental patient" might not cover a person of unsound mind not under treatment. Dr. MORRIS-JONES withdrew his amendment in favour of that proposed by the Minister. Dr. VERNON DAVIES approved the amendment, but Dr. FREMANTLE thought the exceptional retention of the word "lunatic" would add a complication to the law and set up a distinctive classification. The committee then accepted the Minister's amendment, and Clause 20 was added to the bill with that alteration.

The committee accepted, on behalf of Miss LAWRENCE, a revised definition of the words "person in charge." This is now declared to be "in relation to a person received or about to be received under this or any local Act as a voluntary or temporary patient (not being a person received, or about to be received, as a single patient) the medical superintendent or other person in charge of the institution, hospital, home, or place into which he is, or is about to be, so received, and in relation to a person so received, or about to be so received as a single patient, the person into whose charge he is, or is about to be, so received."

On Mr. GREENWOOD'S motion the committee deleted the subsection which extended "local authority" to include the Lancashire Mental Hospitals Board, the West Riding Mental Hospitals Board, and the Staffs Mental Hospitals Board. He gave a firm assurance that before any rules affecting these bodies were made by the Board of Control he would take into consultation not only the hospitals boards but the county boroughs concerned.

Clause 21 was added to the bill. Clause 22 states: "This Act shall not apply to Scotland or Northern Ireland." Miss LAWRENCE explained that the legislation on the subject in Scotland was different and more advanced. The United Kingdom Parliament could not legislate on this subject for Northern Ireland. This clause was added to the bill, and the committee approved the

financial provisions of the bill. Mr. GREENWOOD said local authorities would not be precluded from coming to the Government at the end of the first block-grant period for a revision of that grant on the ground of additional expenditure under the bill. Much of the expenditure would not be new, but the result of a new way of performing old duties.

Mr. ANGELL moved that notwithstanding anything contained in the West Riding of Yorkshire Asylums Act, 1912, any of the powers and duties conferred or imposed by this Act upon a local authority might, after consultation with the West Riding of Yorkshire Mental Hospitals Board, and with the approval of the Board of Control, be exercised and performed by the council of any county borough in the West Riding of Yorkshire. He said that under the 1912 Act the exercise of such powers by the boroughs was excluded. The county boroughs provided such treatment now, and were well qualified to exercise such powers. If they were not given them formally the object of the bill would be defeated, that object being to dissociate the treatment of mental illness from the stigma of lunacy.

Mr. GREENWOOD said this controversy was acute in the West Riding, and he advised the committee to leave it alone. Certain county boroughs felt that the influence of the West Riding County Council was too strong on the West Riding Mental Hospitals Board, but their proper course was to attempt to secure an amendment of the local Act setting up that Board, not to spatchcock an amendment into this bill. The bill would now allow the practical needs of the situation to be met by the Minister making rules and bringing the parties concerned into consultation.

The proposed new clause was rejected without a division.

Mr. GREENWOOD accepted the intention of an amendment from Dr. Fremantle to provide for the annual audit of the accounts of each licensed house, and proposed a new form of words for this purpose, which the committee accepted.

Dr. VERNON DAVIES had an amendment to propose that in the form of recommendation for temporary treatment the certifying practitioner should fill in a declaration stating the grounds on which he had formed his conclusions.

While accepting the spirit of this, Mr. GREENWOOD suggested a new form which would put the classification of grounds of opinion into a footnote to the schedule, instructing the signatory to distinguish between facts based on his own observation and statements of fact based upon communications made to him by others.

Dr. FREMANTLE remarked that, in preparing certificates, the profession tended to be "fluffy" in language. It was a good thing to have to state facts.

The committee added the footnote proposed by Mr. Greenwood, and the forms of recommendation for temporary treatment were added to the bill with slight amendments.

Discussion of the other schedules was postponed till April 3rd.

Patients Received and Discharged by the Board of Control.

Mr. GREENWOOD, on March 27th, gave Mr. Kinley the following figures concerning patients received and discharged by the Board of Control.

	Admissions (excluding Transfers).	Discharges (excluding Transfers).
1920	22,325	10,505
1921	22,709	10,925
1922	23,087	11,024
1923	23,012	10,768
1924	21,251	11,499
1925	21,751	10,934
1926	21,900	10,731
1927	21,878	10,709
1928	22,352	10,649
1929	22,024	10,726

The Board had no similar figures regarding patients received into institutions under the Mental Deficiency Act. The average annual number of certified patients discharged as "recovered" from institutions under the Lunacy Acts during the years 1920–29 was 7,119. Similar figures were not available under the Mental Deficiency Act. A certain number of patients were discharged, but could not be discharged as "recovered."

Small-pox.

In reply to Mr. Groves, on March 27th, Mr. GREENWOOD stated that he was unaware that in many parts of London pressure had been exercised by employers of labour to get their employees vaccinated, in several instances at the request of the local medical officer of health. He knew medical officers of health advised the vaccination or revaccination of persons who had been in contact with small-pox, and he would not be justified in interfering with the discretion of medical officers of health in this matter. During 1929 twenty-three deaths were registered in England and Wales in which the words "vaccination," "vaccinia," or "post-vaccinal encephalitis" appeared in the certificate. In one case of these the certificate stated that these conditions were a contributory cause of death. The ages of the [illegible] ranged from 46 months to 16 years. Fourteen other [illegible] within four weeks of vaccination, but in at least nine [illegible] fatal issue.

Replying, on March 27th, to Mr. Freeman, Mr. GREENWOOD said he had seen a circular letter sent by the medical officer of health for Bethnal Green to medical practitioners there, asking them, when notifying cases of chicken-pox, to indicate whether the patient has been vaccinated or not, in order to facilitate inquiries into the prevalence of small-pox in the borough. His department had not suggested sending the circular, nor did he know to what extent other medical officers had taken the same course. Mr. FREEMAN suggested that vaccinated cases of chicken-pox were automatically diagnosed as chicken-pox, while unvaccinated cases might be rediagnosed as small-pox. Mr. GREENWOOD said he was unaware of this, and had no authority to direct, as Mr. Freeman suggested, that cases of small-pox should be diagnosed entirely on the symptoms and not on the presence or absence of vaccination marks. This was a matter for the medical practitioner in attendance.

Medical Officers in the Army.

In a written reply to Mr. Vernon Davies on March 26th, Mr. SHAW gave particulars concerning medical officers in the Army as under.

Table showing the total number of Regular Officers, Royal Army Medical Corps, serving in the Army by years from 1923 inclusive, together with the number who joined and the number who left the Service each year.

Year.	Strength on January 1st.	Joined.	Retired, Resigned, or Died.
1923	889	11	89
1924	911	12	55
1925	870	9	47
1926	832	13	52
1927	793	25	38
1928	780	28	54
1929	754	28	32

Grants to Voluntary Societies for the Welfare of the Blind.—In reply to Mr. C. Williams, on March 20th, Mr. GREENWOOD said the grants payable to voluntary societies for the welfare of the blind during the current financial year had already been paid in the majority of cases. It [illegible] grants would be paid before March 31st. [illegible] Iceland-Thoyte, Mr. Greenwood said he was unable [illegible] likely to be experienced by voluntary associations owing to the change effected by the Local Government Act. These associations had received a year's Exchequer grant during the present year, and would receive a full year's contribution from the local authorities during the coming and succeeding years. He saw no reason to reconsider the scheme under Section 102 (1) of the Act. Replying to a suggestion that many county councils and voluntary associations considered they would lose six months' grant, he said he had done his best to explain that this was really not so.

Slum Clearance.—Mr. GREENWOOD said, on March 20th, in reply to Major Nathan, that he hoped to introduce the bill dealing with slum clearance at an early date. Meanwhile, he was holding up approval of schemes for rehousing only when the law did not permit him to give permission to local authorities. He had approved schemes which did not conflict with the law.

Royal Veterinary College.—Mr. NOEL BUXTON stated, in reply to Captain Crookshank on March 20th, that the Development Commissioners had recommended, and the Treasury had approved, subject to conditions, a grant not exceeding £100,000, on a pound for pound basis, to the governors of the Royal Veterinary College for reconstruction of the college on the present site.

Proposed Abolition of Speed Limit for Private Motor Cars.—On March 21st the committee of the House of Commons which is considering the Road Traffic Bill approved the proposal of that bill to abolish the speed limit for private motor cars. An amendment by Dr. Salter to make the legal limit thirty-five miles an hour was negatived without a division.

Milk Supplied to School Children.—Sir C. TREVELYAN told Dr. Marion Phillips, on March 27th, that he was aware of the proved value of milk in the diet of children, and an increasing number of children received milk at school, either under schemes organized by the teachers through the National Milk Publicity Council or under arrangements made with the local education authority. In Birmingham over 3,250,000 bottles of milk were supplied to school children in 1928, representing a daily average of over 15,000 children. In Leeds more than half the school children received milk under arrangements made by local authorities.

Notes in Brief.

Mr. Greenwood, on March 27th, stated that it was not the practice at English ports to require a certificate that imports of oleo oil and oleo stearine, used in margarine, were derived from animals free from disease. This certificate was necessary in Scottish ports, and the difference was now under consideration with a view to action.

A petition for abolishing the death penalty, signed by 83,531 British subjects and various local bodies, has been presented in the House of Commons by Commander Kenworthy.

Sir C. Trevelyan told Miss Lee, on March 27th that the recommendations of the report of the Mental Deficiency Committee involved important legislative changes. He was not yet in a position to indicate the attitude of the Government towards that report.

Universities and Colleges.

UNIVERSITY OF LONDON.

THE University College Committee has re-elected Viscount Chelmsford and Sir John Rose Bradford, F.R.C.P., as its chairman and vice-chairman respectively for 1930-31.

UNIVERSITY OF LEEDS.

THE following candidates have been approved at the examinations indicated:

M.D.—H. G. Garland (with distinction) R. Marinkovitch, J. M. Robson.
CH.M.—L. N. Pyrah.
FINAL M.B., CH.B.—*Part I:* J. E. Atwell, P. E. Allison, E. L. Brittain, J. M. P. Clark, J. L. Coleman, J. Fielding, J. J. Fry, R. A. Hall, G. P. Holderness, J. M. Holmes, G. Hyman, A. G. James, D. A. James, G. Marquis, H. Mattison, B. S. Platt, M. R. Potter, S. Rosenbloom, J. G. Ross, N. Ross, J. Schofield, B. Schroeder, P. Science, C. K. Shain, J. Shapiro, J. Shernovitch, P. Staub. *Part II (Old Regulations):* G. Hirst, Eugenie C. Illingworth. *Part III (Old Regulations):* W. H. Craven, Eugenie C. Illingworth, S. Rosenberg, L. Seaton, W. P. Stuart (second class honours), S. Thompson. *Parts II and III (New Regulations):* Bessie Brown (second-class honours), W. R. Everatt, J. F. Galpine, R. G. S. Meadley.
D.P.H.—G. M. D. Lobban.

The following scholarship and prizes have been awarded:

Infirmary Scholarship and Littlewood Prize: H. S. Shacksmith. Scattergood Prize: M. Ellis. Hardwick Prize: L. Seaton. Edward Ward Memorial Prize: L. Seaton. Foyle Prize: G. P. Butler.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

Post-Graduate Course.

ARRANGEMENTS are being made for a three weeks' post-graduate course, on the same lines as in former years, to be held from September 15th to October 4th. A limited number of members of the class can be accommodated in the College rooms or, in the case of women, at Trinity Hall.

CONJOINT BOARD IN SCOTLAND.

THE following have been admitted Diplomates in Public Health:

A. A. Hamilton, S. S. Mirza, C. W. Clayson, H. C. Mehta, W. A. McE. Stewart, J. L. Chisholm, D. A. Fraser.

The following candidates have passed Part I:

G. H. H. Maxwell, W. D. Bertram, E. L. *Godfrey*, R. H. Dawson, Margaret B. McLaren, Dorothy D. W. Brander, Anna M. M. Kerr, T. P. Anmal, Winnifred N. Henderson, Jessie E. M. Munro, J. A. Burgess, A. D. Gorman.

Medical News.

A BANQUET will be held at the Mansion House, London, on April 8th, with H.R.H. the Duke of York presiding, in aid of the fund which the Right Hon. Sir Leslie Wilson is raising to meet the cost of alterations and extensions in the Hospital for Tropical Diseases, Gordon Street, Endsleigh Gardens, W.C. The medical superintendent, Dr. W. E. *Cooke*, has just returned from his five months' tour of Malay, India, and Ceylon.

A NEW health centre, erected and equipped by the Willesden Urban District Council at Harrow Road, Stonebridge, N.W., will be opened at 2.30 p.m. on Tuesday next, April 8th, by the Minister of Health, the Right Hon. Arthur Greenwood, M.P.

PROFESSOR MURDOCH of Brussels will give a lecture at 6 p.m. on May 8th at the British Institute of Radiology, 32, Welbeck Street, on recent advances in radium therapy, with special reference to the measurement of dosage. All medical practitioners interested will be welcome.

A SHORT course of lectures on functional nervous disorders for practitioners and medical students will be given at the Tavistock Square Clinic for Functional Nervous Disorders, 51, Tavistock Square, London, W.C.1, from May 19th to 31st inclusive. The fee for the course is £2 2s. for practitioners and 10s. 6d. for students.

A TWO weeks' post-graduate course in cardiology will be held at the Liverpool and District Hospital for Diseases of the Heart from April 29th to May 12th. Lectures will be given on various aspects of heart disease, and there will be clinical and cardiographic demonstrations. The fee for the course is one guinea, and its membership is limited to twenty. Further information may be obtained from Miss Lewis, Liverpool and District Hospital for Diseases of the Heart, Oxford Street, Liverpool.

THE Fellowship of Medicine announces that there will be an all-day post-graduate course at the Central London Throat, Nose and Ear Hospital, Gray's Inn Road, from April 28th to May 24th, including demonstrations, operations, and lectures.

A two weeks' course in diseases of infants will be held at the Infants Hospital, Vincent Square, from April 22th to May 11th, for medical officers of welfare centres and others interested, the number being limited to fifteen. Each afternoon from 2 o'clock onwards there will be demonstrations and special lectures, and during the course visits will be paid to the United Dairies Pasteurizing Plant, and to the Venereal Disease Centre, Thavies Inn, for syphilitic infants. A course in psychological medicine will be held at the Maudsley Hospital, Denmark Hill, from April 28th to May 30th, consisting of special lectures every afternoon and clinical instruction. In preparation for the M.R.C.P. examination there will be a course of lectures from May 13th to July 4th, on Tuesday and Friday evenings at 8.30 p.m., at the Medical Society lecture room; in addition, there will be two ophthalmic demonstrations. Syllabuses for these courses may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE honorary secretary of the Beit Memorial Fellowships for Medical Research announces in our advertisement pages that an election for Junior Fellows will take place in July next. The successful candidates will be required to begin work in October. The Junior Fellowships are of the annual value of £400, and the usual term is for three years. Full information and forms of application may be obtained from Sir James K. Fowler, M.D., 35, Clarges Street, London, W.1.

IN connexion with the first International Congress of Microbiology which is to be held in Paris from July 26th to 25th, an itinerary with list of prices may be obtained from Thomas Cook and Son, Ltd., Berkeley Street, W.1, or from any of their branches. The proposed arrangements have been made in consultation with the National Committee for Great Britain and Ireland of the International Society for Microbiology, of which the secretary is Dr. R. St. John-Brooks, Lister Institute, Chelsea Bridge Road, S.W.1.

THE tenth congress of the International Society of Urology will be held at Madrid from April 7th to 12th, under the presidency of Professor Leonardo de la Peña. The *Transactions*, which contain abstracts of the papers in English, French, and Italian, have already been sent to members of the society.

THE Flemish Congress of Natural Sciences and Medicine will be held at Antwerp from April 25th to 28th. Further information can be obtained from the secretary, Dr. P. De Maeyer, Rue Guimard 15, Ghent.

THE Memorandum on British Patent Law Reform, which was compiled by a joint committee representing the Association of British Chemical Manufacturers, the Chemical Society, the Institute of Chemistry, and the Institute of Chemical Engineers, and submitted to the Board of Trade Patents Committee, has now been published, and copies may be obtained (price 1s.) from the Association of British Chemical Manufacturers, 166, Piccadilly, London, W.1. The committee includes in its Memorandum the details of a scheme to be administered by some department of State, for the dedication to the British public of medical patents. A similar scheme has been approved by the Council of the British Medical Association, and is being reported to the Representative Body.

THE International Labour Office has issued from 12, Victoria Street, S.W.1, seven further brochures in the series Occupation and Health. The subjects dealt with are No. 177, blood changes due to occupation; No. 178, clothing or garment trade; No. 179, cork and linoleum industry; No. 180, cotton industry; No. 181, cyanogen and its compounds; No. 182, cerium; and No. 183, coal tar. With brochure No. 183 the subjects coming under the letter "C" are complete, and can therefore be bound.

An official communication has been received, as we go to press, from the Radium Commission reporting on the progress of the national organization which it is engaged in setting up. In pursuance of its policy of concentrating national radium at a limited number of centres where there are medical schools with complete clinical courses, twelve "National Radium Centres" have been nominated as follows: Birmingham, Bristol, Leeds, Liverpool, Manchester, Newcastle, and Sheffield; Aberdeen, Dundee, Edinburgh, and Glasgow; Cardiff. London has been treated as a separate problem, in view of its position as the metropolis of the whole country, and steps have been taken to organize two centres to carry out special work of general and national importance. One centre is at the Westminster Hospital, and the other, for the development of post-graduate teaching in radium therapy, is at the London Radium Institute and the Mount Vernon Hospital, Northwood, which are being reorganized as a joint teaching centre, styled the "Mount Vernon and Radium Institute." In all, some seventeen grams of radium have so far been ordered and provisionally allocated to national centres. The full text of the Radium Commission's statement will appear in our next issue.

THE KING has confirmed the appointment of Dr. G. Cecil Strathairn, Director of Health, to be a nominated official member of the Legislative Council of the Colony of Cyprus.

DURING 1928 more than fifty lectures on malaria, illustrated with lantern slides, were delivered in the Chinese schools and clubs in Perak and other towns in Malaya, about 10,000 people attending them. Audiences were recruited by an attendant perambulating the towns with a handbell. The importance of the crusade is illustrated by the fact that, out of 34,153 deaths in the Federated Malay States in 1925, no fewer than 14,377 were registered as being due to fever.

THE Grand Prix of the Société des Gens de Lettres has been awarded this year to a medical man, Dr. Pierre Dominique Jacques Lucchini, who writes under the name of Pierre Dominique.

PROFESSOR SEMASCHKO of Moscow has resigned his post of commissioner of public health.

THE Académie des Sciences has decided to recommend the Institut de France to award the Osiris prize of 200,000 francs to Professor Gley, who holds the chair of physiology at the Collège de France.

DR. MORAX, ophthalmologist to the Hôpital Lariboisière, has been elected a member of the Académie de Médecine in the surgical section.

DURING the academic year 1928–29, 1,069 diplomas of doctor in medicine were conferred by the various French faculties.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

SUPPLY OF PRESSURE APPLICATORS IN THE FINSEN LIGHT TREATMENT.

"J. B." writes: I should be glad to learn where it is possible to obtain pressure applicators for circulating water, such as are used in the Finsen light treatment. I have applied to one or two electrical firms, but they apparently wish to sell the whole Finsen-Reyn apparatus, and just at present I want applicators only.

TREATMENT OF ASTHMA.

"A. V." writes to suggest that "M. E. P." (March 22nd, p. 575) should try the mercury vapour lamp at 2 ft., beginning with two minutes and leading up to six minutes for twelve applications, and repeating the treatment after a month's rest.

ENLARGED PROSTATE AND PROSTATECTOMY.

"H. W." writes: I have to record one case where inunction and massage of the prostate per rectum with a neutral petroleum unguent of iodine greatly relieved the frequency of micturition; the stream of urine passed is much fuller, indicating that the iodine is having a local effect. Since we often see glandular and indurated masses disappear with massage and iodine in other situations, can we not hope by this or other methods to avoid operative intervention, in some cases at least? I should be glad to have an expression of opinion with regard to the permanent effect of remedies other than surgical treatment, which has its limitations. I note in the *Journal* of March 15th (p. 494) that reference is made to static electricity as a method of reducing the hypertrophy and symptoms.

LETTERS, NOTES, ETC.

EARLY DIAGNOSIS OF TUBERCULOSIS.

DR. W. M. CROFTON (University College, Dublin) writes: The making of an early diagnosis in tuberculous disease is indeed of first importance. But eliciting of physical signs in a lung, however delicate, is not making an early diagnosis; it is making a diagnosis of well-established disease, and this diagnosis is only confirmed by the finding of tubercle bacilli. At this stage of the disease apparently there is complete scepticism about the capacity to cure it by the methods at present in use. Wingfield writes: "When c[illegible] ressed to the extent of being clinically [illegible] be eventually almost universally fatal. [illegible] most universal opinion among tuberculosis experts, as elicited by Gordon Tippett. No one can make an early diagnosis. No one can say a case is cured, for so many cases apparently cured break down again. There is therefore no sound criterion of cure. Everybody connected with the disease is in a hopeless state of mind about it. Moreover, they are so pursued by ancient bogies that the only test, the subcutaneous tuberculin test, which has been proved to be reliable by hundreds of thousands of post-mortems in cattle, must not be used, since it is dangerous in human beings. The way general and focal reactions after tuberculin inoculation are spoken of and written about one would think they were uniformly fatal, instead of being manifestations of the immunizing process which leaves the patient on a higher plane of resistance to the tubercle bacillus than before such a reaction had occurred. There are, then, two kinds of opinion about the test: (1) that of those who do not believe in its absolute diagnostic value, and (2) that of those who believe in its diagnostic value, but think it too dangerous to use in human beings. The first class had better consult their veterinary brethren and ascertain its almost complete reliability, and the second ought to follow the work of those who use tuberculin in their treatment of the disease, and so get rid of this absurd phobia, which is holding up so seriously our control of the disease. Apart from it, there is no reliable test for either the early diagnosis of the disease or the cure of it.

MEASLES IN LATER LIFE.

DR. R. BALFOUR GRAHAM (Leven, Fife) writes: With reference to the case of measles at the age of 57, described by Professor A. J. Hall in the *Journal* of March 29th (p. 586), might I record a more remarkable one in point of age in a spinster, aged 76? Had it not been that there was measles about, and that the day-attendant of the old lady had a case of measles in her own house (from which source, perhaps, came the infection), I should have doubted my diagnosis, but to make sure I asked Dr. J. M. Johnstone of Leven to see the case, and he at once confirmed it. There was nothing very remarkable about the course of the illness, the symptoms of which resembled pretty much those in Professor Hall's case, the only noteworthy point being that my patient made a complete and speedy recovery after about ten days' illness. She is not sure if she has ever had measles before, but a second attack is not uncommon in my experience.

DR. N. DOUGLAS MACKAY (Aberfeldy) records two cases of measles which occurred in his practice some years ago. The first, a woman aged 74, was infected during a local epidemic. Beyond a mild bronchial catarrh, too slight to be dignified with the name of complication, the attack ran a normal course, and the patient made a perfect recovery. The second case, in a woman aged 78, was sporadic so far as this district was concerned, and the only channel by which infection could have reached the patient was a daughter who, two weeks or so before the commencement of the attack, had returned home from visiting in a house where several children were down with measles. This was the only possible source that could be traced, and it was noteworthy that the daughter, a middle-aged woman, did not herself develop the complaint. Here, again, the disease ran a normal uncomplicated course, and ended in the perfect recovery of the patient. Both these old women were of the healthy, robust type, and each survived her unusual experience for several years.

DR. J. H. DREW (Weston-super-Mare) writes: It may be of interest to state that I have seen in the last few years three cases of measles in women aged 64, 68, and 55 respectively. The patient aged 64 was infected from a great-nephew, whom she had been nursing—eighteen days from rash to rash. She had a very profuse eruption, and ran a temperature of over 105° F. for four days, with severe bronchitis. The woman aged 68 was infected from children in the house, apparently from casual contact on the stairs; here again the attack was severe. The last case, in a woman of 55, occurred a few weeks ago, and was of a milder type, the temperature not exceeding 103.5°, and the bronchitis being slight.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50, 52, 53, 56, 57, and 58 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *107*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

317. The Heart and Athletic Strain.

F. DEUTSCH (*Wien. klin. Woch.*, January 9th, 1930, p. 51) defines the "athlete's heart" as a condition of permanent cardiac enlargement following overstrain. The condition may be due to dilatation secondary to myocardial weakness, and be associated with hypertrophy. Transient enlargement is believed to follow severe physical exertion inmost cases immediately, but usually, within twenty-four hours after the strain has ceased, the heart becomes smaller than before. The degree of reduction varies greatly, and depends more upon the condition of the general circulation than upon the heart itself. Muscular exercise by flooding the skeletal muscles with blood diminishes the volume of blood in the spleen and liver, and lowers the peripheral blood pressure. After exercise the muscular capillaries contract and blood returns to the abdominal viscera, while metabolic activity is increased; sometimes the transient cardiac reduction gives place to actual enlargement, but this condition is not necessarily the "athlete's heart," although chronic cardiac dilatation due to diminished pulmonary capacity may be so described. As a means of predicting which type of heart will become enlarged under physical strain Deutsch recommends the following method. The size of the heart is determined by percussion and orthodiagrammatic measurements, and its weight is calculated. The weight of the heart increases with age, and one object of physical training is to increase the thoracic circumference. The size of the heart is largely dependent on these factors, and less on the body weight. Small hearts are frequently found in very tall subjects and in highly trained athletes without any diminution of efficiency, but as a rule heart weight is proportional to body weight. In the estimation, time is an important factor, for a fully trained athlete's heart, examined shortly after a strenuous effort, may vary considerably in size in a short period. Two or three days should elapse between the last strenuous exercise and the examination. Repeated control examinations of athletes at various times show that during the entire sport season the heart may be enlarged, returning to normal size when training ceases. If cardiac enlargement persists, "athlete's heart" may be suspected. Definite pathological signs are unusual, but auscultation may reveal an accentuated pulmonary second sound or a ringing aortic second sound. Systolic bruits are absent, and there is no evidence of myocardial weakness. A normal athlete's pulse is remarkably slow, a rate of 56 being common and indicating a healthy circulation, able to withstand strenuous exercise. Hypotension is also favourable, since hypertension may be due to "athlete's heart," though not pathognomonic. As a preliminary to entry on athletic contests Deutsch determines pulse acceleration after exertion, the candidate flexing the knees fully ten times a minute, or marking time at the rate of two steps a second. The rate then should not be higher than 100 or 120 beats a minute. Two or three minutes after the test the tachycardia should have subsided: if it persists, the heart is unfit for severe exercise. After these exercises an untrained person should not have a rise of more than 40 mm., and one who is trained not more than 10 mm. of mercury. In both cases the blood pressure should return to normal in less than three minutes. After exercise there should be little or no decrease in the lung capacity, and after strenuous exertion only transient diminution; in heart lesions it is frequently greatly reduced. Chest expansion affords a simple method of measuring pulmonary capacity.

318. Primary Meningitis and Meningo-encephalitis in Mumps.

R. J. WEISSENBACH, G. BASCH, and MARIANNE BASCH (*Ann. de Méd.*, January, 1930, p. 5) point out that the virus of mumps can attack other organs before being localized in the parotid gland and in the absence of any glandular involvement. Among these extraglandular localizations of the initial septicaemia and the clinical manifestations are meningitis and meningo-encephalitis. Two cases of such conditions are recorded in detail. One was of a purely meningeal type and primary, the parotitis becoming manifest on the fourth day of the illness. The other was also primary, the mumps appearing on the third day; it was of the meningo-encephalitic type, a right hemiplegia developing with transitory aphasia and neuralgia of the trigeminal nerve. These primary meningeal attacks are divided into two groups—those followed by and those not followed by mumps. In the meningeal type the glandular involvement is relatively early; it is often unilateral, always of a slight nature, and of short duration. In the second type the virus acts in a manner similar to that of epidemic encephalitis and attacks the bulbo-protuberantial nuclei or even more differentiated regions of the hemispheres; very occasionally the attack resembles coma or apoplexy. Short notes on cases illustrating each type are given. The authors consider that in a meningitis occurring in full health, after eliminating the more frequent forms, a diagnosis of meningitis due to a parotitis virus should be entertained. A most careful examination should be made of the parotid, submaxillary, and sublingual regions, and of the opening of Stenon's duct. The cerebro-spinal fluid affords the best diagnostic evidence; it reveals a clear, sterile, non-xanthochromic fluid containing a marked mononuclear lymphocytosis, a low albumin and chloride content, but an almost normal sugar figure, and absence of fibrin. The meningites under consideration must be differentiated from the tuberculous, syphilitic, and meningococcal forms, epidemic encephalitis and Heine-Medin's disease. The prognosis is particularly favourable; sequels are exceptionally rare, and, if present, last only a few weeks.

319. Vincent's Angina and Fuso-spirochaetal Pulmonary Disease.

THERE is considerable evidence that the anaerobic organisms present in Vincent's angina may under certain conditions initiate a severe or even fatal pulmonary infection. Though these infections generally occur as a complication of the angina, they are occasionally primary. D. T. SMITH (*Journ. Amer. Med. Assoc.*, January 4th, 1930, p. 23) cites several such cases from the literature, and reports three personal ones. Two of these were primary infections of the pharynx with subsequent extension into the lungs. The third was primary in the lungs and began four days after contact with a case of Vincent's angina. The sputum in the last case was thick, green, purulent, odourless, and resembled tuberculous sputum, though at no time were tubercle bacilli demonstrated either by smear or guinea-pig inoculation. Both the large and the small types of the fusiform bacilli were isolated. The spirochaetes were predominantly of the *Spirochaeta vincenti* type, with small numbers of *Treponema microdentium*. Smith states that Vincent's angina is a relatively common and widespread disease, and that pulmonary complications due to these fuso-spirochaetal organisms are by no means infrequent. The complicating pulmonary lesions, often confused with tuberculosis, may take the form of pulmonary gangrene and abscess, ulceration of the bronchi, lobar pneumonia, broncho-pneumonia, and empyema. Many patients recover spontaneously, but in some the condition ends fatally. It is advisable to treat all cases in which the organisms can be demonstrated in the sputum with either neo-arsphenamine or sulpharsphenamine. To obtain the best results the diagnosis should be made and the arsenic given before any appreciable destruction of lung tissue occurs. In all the three present cases recovery was prompt after the administration of sulpharsphenamine.

320. Chronic Morphine Poisoning.

K. MORINAKA (*National Medical Journal of China*, December, 1929, p. 764) describes a prolonged investigation of chronic morphine intoxication in opium smokers. Men smokers are ten times more numerous than women smokers, and the incidence of symptoms of poisoning is greatest between the ages of 31 and 40. Of the reasons given for starting the habit sickness ranks highest, and among the causes of ill health digestive disturbances are nearly twice as frequent as other diseases, respiratory troubles coming second. Opium is resorted to as a remedy for abdominal pain, diarrhœa, and vomiting, particularly in the country districts where medical advice is not available. The author gives a series of tables showing the results of an investigation into the degree of gastric acidity during a period of abstinence, as compared with a period under the influence of morphine. It appears that the secretory function is generally normal while the patient is under the influence of morphine, but is markedly increased when the drug is withheld, and this increase cannot be effectively controlled by atropine. Radiographs of a test meal are reproduced indicating that the stomach is in a state of hypertension with strong and repeated peristalsis during the abstinent period, while the basal metabolism increases by 60 per cent. The excretion of phosphoric acid and organic phosphorus is markedly raised during abstinence.

321. Intestinal Complications of Undulant Fever.

W. A. GRIFFIN (*New Eng. Journ. Med.*, February 13th, 1930, p. 324) records a case of chronic fever in a boy, aged 12, in whom all the laboratory tests, except for undulant fever, were negative. He showed definite signs of intestinal ulceration, which improved markedly in two months on intensive helio-therapy, with the administration of tomato juice and cod-liver oil, and accompanying the improvement the patient became symptom-free. There was a history of three weeks' fever in 1926, recurring in 1928 with marked anorexia and complaint of a full feeling while eating. There was no diarrhoea. Tests for typhoid, malaria, and tuberculosis were negative, and the diagnosis of undulant fever was based upon agglutination tests, the organism being later cultured from the blood. *X*-ray films following a barium meal revealed from the sixth to the eighth hour a very marked filling defect in the caecum and to a less extent of the ascending colon, especially at the hepatic flexure, and the general irritability of the bowel was shown by the twenty-four-hour film, when there was practically no barium left. After two months' treatment the filling defects had almost disappeared, and the general intestinal irritability had largely subsided. While it is not claimed that in all cases of undulant fever there are ulcerations in the intestines, the fact is significant that this patient immediately improved with the disappearance of all symptoms upon treatment directed to the intestines; the author considers that the case affords a possible explanation of the symptoms of undulant fever.

322. The Association of Diabetes and Tuberculosis.

J. LEITNER (*Zeit. f. Tuberculose*, February, 1930, p. 30) discusses 12 cases of diabetes occurring among 3,500 cases of phthisis. Diabetes is apparently usually the primary disease, which, by lowering the general resistance, increases susceptibility to tubercle. The conditions influence each other unfavourably; the lowered vitality of the diabetic and his restricted diet, combined with the anorexia of the phthisical, made recovery difficult. Tuberculosis in diabetes causes few symptoms and signs: the initial rise in temperature is marked by the diabetic temperature, the sputum is scanty and contains few bacilli, and auscultation reveals little; consequently the systematic *x*-ray examination of the chests of diabetic patients is strongly advocated. Of the author's 12 cases, in 8 the diabetes was definitely primary, and in 3 both conditions were discovered simultaneously; all tended to cavity formation, most had family histories relating to one or the other, and the age incidence was between 38 and 63. No patients died in the sanatorium, but some left with a very bad prognosis. Until recently only conservative measures had been employed; lately good results are reported as following the use of insulin. Leitner adds, however, that this should be given only when really required, and then be begun cautiously; in many cases dieting does all that is necessary. When the metabolic condition improves, the lung condition should be tackled, preferably by pneumothorax; as the pulmonary disease grows less the carbohydrate tolerance will rise. The author has lately used a new sugar substitute, s onon, which is a product of the reduction of glucose and fructose; it has a pleasant sweet taste and high calorie content, and is said to cause neither glycaemia nor glycosuria.

323. Nephritis with Hypochloraemia.

C. ACHARD (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, January 27th, 1930, p. 27) reports a case of acute nephritis in a woman, aged 37, who had had rigors, abdominal pain, frequency and pain on micturition, and, later, acute suppression. Examination of the urine had shown 2 grams of albumin per litre and an abundance of blood. This was her fourth attack in twenty months. During the first forty-eight hours in hospital she had vomiting and sweating attacks, passed 100 c.cm. of urine with 5.37 grams of urea per litre, had 2 grams per litre of blood urea, and her temperature dropped from 102° to 93°. She was cupped and given lactose drinks and injections of hypertonic glucose serum. Three days later she passed 300 c.cm. of urine containing 8.10 grams of urea per litre; her vomit (560 c.cm.) contained 7.3 grams of urea and 2.10 grams of sodium chloride per litre. The blood urea rose to 3.24 grams; the alkaline reserve figure was 34.7 grams and the serum chloride figure 2.59 grams. The urine acidity figure was 5.7. She was given 20 grams of sodium chloride by the mouth, and 7 grams by injection in 500 c.cm. of hypertonic solution; 27 grams were given daily on three consecutive days, followed by 12 grams on the next three days. The amount of urine increased, the urea content decreased abruptly, the blood urea diminished slowly, and the serum chloride increased gradually to above the normal level. Treatment was then remitted for nine days. The blood urea increased a little, while the serum chloride diminished slightly. The patient then received 5 grams of sodium chloride daily, and five days later had 0.38 gram of blood urea, 3.63 grams of serum chloride, and 61.1 grams of alkaline reserve. She was discharged, improved, after further treatment for six weeks, with instructions to remain on a diet low in protein and moderately salted.

Surgery.

324. Treatment of Adenitis by Diathermy.

P. RAVAUT and Mlle LANDOWSKI (*Bull. Soc. Française de Derm. et de Syph.*, December, 1929, p. 1248), encouraged by the good results obtained in the treatment of actinomycosis and keloid acne by the diathermo-coagulant drain, have employed this method in numerous cases of chronic suppurating glands, some with and some without sinuses. When the glands were multiple, deep, and the patient sensitive, anaesthesia by ethyl chloride was used; the authors hardly ever employ local anaesthesia because the saline infiltration of the tissues modifies the conduction of the electric current and may harmfully widen the limits of the coagulating action. They generally operate without an anaesthetic; the pain is occasionally acute, but it only lasts a few seconds. If the abscess is enclosed the softest point is chosen, the needle attached to the apparatus is inserted so that the centre of the collection is reached, and the current is turned on. As a destructive action is desired they begin with a weak current, which is progressively increased if necessary. The cavity quickly swells up and bulges at the surface; a zone of white coagulation appears round the needle on the skin which increases while the contents of the gland are raised to boiling point. The needle is then briskly withdrawn. In small lesions one insertion only is made, but in extensive cases several attacks may be necessary. Sinuses are treated in the same way. During the following days there occurs a copious discharge; in about ten days the scab is detached, carrying with it skin and coagulated gland tissue, so that a wound is formed lined by gland and dead cellular tissue. Healing is said to be surprisingly rapid; the scars are small and continue to diminish. The authors state that for several years they have had excellent results with this treatment of numerous cases of tuberculous glands of the neck and axilla, and notes are given of successes obtained in other parts of the body.

325. Enterocystoma.

RUTH E. MILLAR and G. ROBERTSON (*Brit. Journ. of Surg.*, January, 1930, p. 373) describe a case of enterocystoma occurring in a girl, aged 8, who four years previously had begun to suffer from pain in the right iliac fossa and epigastrium with severe periodical attacks of vomiting, the vomit being frequently bile-stained. The intervals between the attacks became gradually lessened to a fortnight in duration. O[illegible] laparotomy was performed, [illegible] the caecum, an elongated to[illegible] the long axis of the intestine. It exhibited peristalsis, was intestinal in appearance, and constricted near the middle, both ends being blind, with the lower overlying a normal appendix. The cyst was unilocular and contained two ounces of transparent mucoid fluid; for two-thirds of its length it was connected by a mesentery to the true mesentery of the ileo-caecal angle without any intestinal pedicle existing between them. The growth belonged to the rarest type of enterocystomata, and was probably vitelline in origin, as most of them appear to be. Considerable hypertrophy of the muscle coat existed, and had been progressive over a period of four years. The authors regard this as an explanation of the increasing severity of the attacks, it being conceivable that temporary strong peristalsis of the normal intestine might be shared by the cystoma as an isolated closed segment, the nerve supply of which was similar to, and connected with, that of the normal intestine. After removal the cyst showed active peristalsis even when lying on a cold specimen tray, and the application of warm moist gauze pads excited vigorous contractions, which only ceased after a lapse of two hours. The case is reported because of the rarity of enterocystomata, and as being the least common type of these tumours.

326. Complete Torsion of the Gall-bladder.

G. KETTNER (*Zentralbl. f. Chir.*, March 8th, 1930, p. 339) records an illustrative case, and has collected 17 others from the literature, including 12 mentioned in Fischer's work and more reported by Mathieu, Marinacci, Grunert, and Therstappen respectively. It is easy to understand how such a pendulous organ as the gall-bladder can readily undergo torsion owing to a sudden pressure exerted on it by the diaphragm, the intestine, or some violent movement. In all

cases, including the present one, the patients were elderly women with little fat, flaccid abdominal walls, and enteroptosis—in short, of a constitution which allowed the greatest possible movement to the abdominal contents. When the angle of torsion exceeds 90 degrees the cystic artery becomes occluded and gangrene of the gall-bladder ensues, followed by perforation and peritonitis unless operation is performed in time. Treatment consists in cholecystectomy, which is almost always successful. Kettner's patient was a woman, aged 53, in whom a diagnosis of intestinal volvulus was made and laparotomy performed on the first day of disease. The gall-bladder, which was found to have undergone a torsion of over 180 degrees, was excised, and recovery was uneventful. The walls of the gall-bladder were thickened and studded with haemorrhages, the mucous membrane was necrotic, and several bilirubin calculi were found.

327. Volkmann's Ischaemic Contracture.

L. DURANTE (*Arch. Ital. di Chir.*, February, 1930, p. 429) describes a typical case of Volkmann's ischaemic contracture with concomitant median-ulnar neuritic irritation. The syndrome developed on the tenth day after an incised wound of the bend of the right elbow, involving rupture of the radial and ulnar arteries at their point of origin and the formation of a large pulsating haematoma compressing the forearm. Ligature of the brachial artery on the fiftieth day after the wound cured the haematoma, but the simultaneous excision of the two fibrous bridges between the ends of the ruptured arteries, which interfered with the vascular sympathetic supply, was not followed by any modification of the syndrome. Excision of the perineural sheath of the median and ulnar nerves at the lower third of the forearm was performed four months after the wound, and was followed by the rapid disappearance of all the sensory and trophic symptoms. Almost complete extension of the fingers became possible, even with the hand in extension on the forearm; there was, in fact, an almost complete recovery from Volkmann's syndrome. The author discusses the literature relating to this condition, and concludes that there is evidence for the occurrence with it of a sympathetic neuritis. Presumably, the excision of the perineural sheath tried by Durante in his case, in view of its being indicated in causalgia, is followed by better results when it is performed at the earliest opportunity.

328. Indications for Phrenicectomy.

J. A. MOORE (*Arch. of Surg.*, February, 1930, p. 175), in reviewing 63 cases of pulmonary disease treated by phrenicectomy, states that this treatment was successful in 75 per cent. of cases in which the anatomical result (paralysis and rise of the diaphragm) increased the compression obtained by thoracoplasty; it also increased the amount of relaxation of the lung produced by intercostal neurectomy, and the degree of collapse in artificial pneumothorax. Since phrenicectomy produces only partial rest and relaxation of a diseased lung, paralysis of the hemidiaphragm must be considered as a complement to other methods of treatment. It is frequently useful in the treatment of pulmonary tuberculosis as a complementary procedure to extrapleural thoracoplasty, to the Schede method of thoracoplasty, and to artificial pneumothorax. Phrenicectomy is used as an independent procedure in the treatment of tuberculosis, being indicated in an acute progressive caseous type of tuberculosis when pneumothorax is prevented by adhesions, in chronic types of disease, in early cases of unilateral tuberculosis, in basal tuberculosis, and also for the relief of specific symptoms without the expectation of a cure. Phrenicectomy is also employed in cases of bronchiectasis, in subacute and chronic pulmonary abscess, as a prophylaxis against the development of bronchiectasis after an unresolved pneumonia, in cases of hydatid disease of the lung, for diaphragmatic hernia, to aid in filling in the defect in the wall of the chest after the removal of malignant neoplasms, and in stab or gunshot wounds. Of the 63 cases under review, temporary phrenic nerve interruption by crushing the phrenic nerve and the accessory nerve was performed in 9 cases, the radical phrenicectomy of Goetze in 26 cases, and evulsion or exeresis of Felix in 28 cases. Paralysis of the diaphragm was obtained in 58 cases, and was indeterminate in 5. There was no operative death.

329. Remote Results of Pyloric Resection for Peptic Ulcer.

K. NELLEN (*Deut. Zeit. f. Chir.*, February, 1930, p. 164) records the results of resection of the pyloric antrum (Billroth I and II) for gastric or duodenal ulcer which had been performed in the surgical department of the municipal hospital at Altona during the period 1920–26. Of 43 cases in which the operation had been performed two or more years previously, 36 (84 per cent.) could be regarded as cured, while 7 (16 per cent.) still suffered from more or less severe symptoms. In the great majority of cases the general condition was essentially improved. The individual's power to gain his livelihood was also in most cases restored. In almost all the cases there was reduction of free hydrochloric acid to zero, essential diminution of the total acidity, decided diminution of the gastric movements, and accelerated evacuation of the contents of the stomach. The seven cases which were not cured consisted of constipation (1 case), neurasthenia (2 cases), pulmonary and intestinal tuberculosis (1 case), and suspected recurrence of peptic ulcer (3 cases). It has not, however, yet been possible to verify these diagnoses by necropsy. After subtracting the cases with neurasthenic symptoms, and accidental diseases which could not be attributed to the operation, the proportion of failures was reduced to 6 per cent., a figure which agrees with that of other writers and shows a superiority of resection to other methods. Resection of the pyloric antrum by removal of the ulcer not only prevents the later risks of haemorrhage, perforation, and malignant degeneration, but also produces a chemical and mechanical condition of the stomach which essentially reduces the risk of a relapse.

Therapeutics.

330. Adonidine as a Cardiac Diuretic.

A. SHEDROW (*Journ. Med. Assoc. of South Africa*, February 8th, 1930, p. 75) has made a series of clinical tests of the glucoside adonidine, which is the active principle of *Adonis vernalis*. He has administered this substance to patients between the ages of 65 and 82 suffering from all degrees of cardiac insufficiency due to various causes. The optimum dose was found to be 5 mg.; if this produced no effect, subsequent doses were also useless. The predominant action of adonidine was upon the secretion of urine, the output rapidly rising from 250 c.cm. to 3,000–4,500 c.cm.; this increased secretion continued until the oedema had disappeared. No effect on the urinary secretion was obtained in patients without oedema, nor upon oedemas of renal or hepatic origin. While it is claimed that the drug increases the contractility and excitability of the myocardium, adonidine has no influence upon conductivity; in this way it differs from digitalis, which otherwise possesses similar therapeutic properties. Adonidine has a wider use than novasurol or salyrgan, since the latter are mercurial preparations and may be dangerous if there is much renal or hepatic damage. The indications for the use of this drug are: (1) all cases of heart failure accompanied by oedema, the fluid intake being reduced to one litre daily; (2) to prolong the diuretic effect of digitalis when the latter drug has produced an initial improvement; and (3) when digitalis is without effect or is contraindicated. The administration of adonidine is inadvisable when cardiac failure has advanced to its terminal stages.

331. Treatment of Mumps with the Serum of Convalescents.

P. IVERSEN (*Ugeskrift for Laeger*, February 13th, 1930, p. 187) observed an epidemic of mumps in the winter of 1922–23 in the infectious division of a military hospital. As it soon became evident that the incidence of orchitis was very high, he administered the serum of convalescents to a certain number of the patients in the hope that this complication of mumps would be reduced in frequency. The Danish State Serum Institute prepared a mixed serum from convalescents, from the tenth to the twenty-second day of the disease, nearly all of them having been afebrile for about a week. In order that changes in the character of the epidemic as it proceeded should not vitiate the conclusions drawn from this experiment, only alternate patients were thus treated, every other patient being given an intramuscular injection of 40 c.cm. of the serum. In uncomplicated cases the patients were kept in bed for ten days after the fall of the temperature to normal. The patients who already suffered from orchitis on admission to hospital received no serum, and were classed in a group by themselves. Altogether 293 patients were admitted to hospital. Of the 76 admitted without orchitis before this treatment was started (Group I) 24, or 32 per cent., developed orchitis, which in three cases was bilateral. Group II included the 56 patients admitted to hospital after the adoption of this treatment, but not given it. Group III included the 56 patients given the serum. In Group II there were 16 patients (29 per cent.) who developed orchitis, which was bilateral in 3 cases. In Group III there were 11 patients (20 per cent.) who developed orchitis, which was bilateral in one case. Of the 15 patients in Group IV who had not been treated in bed from the outset and who were already suffering from orchitis on admission to hospital, and who received no serum, as many as 6 had bilateral orchitis. On the other hand, among the 51 patients who developed orchitis

344. Anaesthesia during Labour in Private Practice.

H. SELLHEIM (*Med. Welt*, March 1st, 1930, p. 288) reports replies received from eight leading German gynaecologists who were asked to state their opinions as regards relieving pain during labour in private practice. One could recommend no suitable method, since all, including twilight sleep and regional anaesthesia, required constant medical supervision. No one favoured and five definitely rejected twilight sleep, whether by scopolamine-morphine or the newer methods, such as pernocton, since the presence of a doctor was necessary the whole time. Such long anaesthesia, it was added, is generally unnecessary, and most gynaecologists confine themselves to treating any very severe pain about the end of dilatation and beginning of expulsion, and to ensuring more or less complete anaesthesia for the birth of the head and any episiotomy that may be necessary. Morphine in the earlier stage is advocated by three gynaecologists. One gives as a routine a mixture containing chloral hydrate and morphine hydrochloride, and finds that it hastens rather than hinders the birth; for the passage of the head he prefers chloroform to ether. Two give morphine hypodermically, followed by chloroform, for the birth of the head; one employs a mixture containing scopolamine and pantopon, of which a third may be given at the beginning of the second stage and the rest for the delivery of the head. Two recommend injection of the neighbourhood of the pudendal nerve with a solution of novocain and adrenaline; this lasts two or three hours, does not delay labour, and the technique is said to be easily learned.

Pathology.

345. Frequency of Weil's Disease in Holland.

W. SCHÜFFNER (*Arch. f. Hyg.*, January, 1930, p. 249) reports on 47 cases of Weil's disease diagnosed in the Institute for Tropical Hygiene at Amsterdam between October, 1924, and July, 1929; of these, 11 proved fatal. As regards the mode of infection, 21 of the patients had, five to twelve days before the onset of the disease, either by mishap or with intent to commit suicide, fallen into more or less dirty water, of which they had swallowed and inhaled a good deal. Seven patients were active swimmers, and developed the disease during the bathing season; 5 were sailors, or men engaged in cleaning animal intestines under water; one was a laboratory worker; and the remaining 13 gave no history indicative of the mode of infection. Jaundice developed in 37 patients. The diagnosis was made twelve times by cultivation of *Leptospira icterohaemorrhagiae* from the blood, organs, or urine. Except in fatal cases, blood cultures were positive only before the development of jaundice; positive cultures from the urine appear to have been uncommon. In 35 cases the diagnosis was made by serological tests. The diagnostic titre, for agglutination and lysis, was taken as 1 in 1,000; only two serums reacted in as low a dilution as 1 in 2,500; the remainder had very much higher titres. The author concludes that with the exception of Sumatra, and perhaps Japan, there is no country other than Holland in which so many sporadic, bacteriologically attested cases of Weil's disease have occurred. Whether the canal system is responsible for increasing the chance of infection the author does not decide, but he brings evidence to suggest that infection occurs not by contact with the normal water leptospira, *L. biflexa*, which has assumed virulence in the tissues, but by contact with water that has been contaminated with infective rat's urine.

346. The Ability of Formolized Vaccine to give rise to Allergy.

BUSSEL and MAYZNER (*C. R. Soc. de Biologie*, February 14th, 1930, p. 411) added formol to vaccinia vaccine and incubated the mixture for six weeks at 37° C. For testing its antigenic properties at the end of this time four infants were chosen who had not previously been vaccinated against small-pox. Two of the infants were injected subcutaneously with three doses of 0.5 c.cm. at three-day intervals; the other two were injected intracutaneously with three doses of 0.1 c.cm. at the same intervals. Four weeks after the last injection all the infants were inoculated with living vaccine by the scratch method, and pustules developed at the end of three days. In those infants previously injected subcutaneously the pustules were transformed in two or three days into crusts, but in those infants previously injected intracutaneously the pustules reached a diameter of 2 cm., and were surrounded by congestion and infiltration; the temperature rose to 102° and remained elevated for three days; after this time the pustules became covered with voluminous crusts and the local inflammation subsided. Since the treatment with formolized vaccine led to an accelerated reaction on the subsequent inoculation of living vaccine, the authors concluded that it had given rise to allergy, and therefore must have preserved its antigenic properties. To test this conclusion they made a series of intradermal inoculations with 0.1 c.cm. of formolized vaccine, diluted 1 in 50 to 1 in 200, on subjects some of whom had previously been vaccinated in the ordinary way with living vaccine. Altogether 53 vaccinated and 45 non-vaccinated subjects were tested. The reactions were studied after twenty-four and forty-eight hours, after which time they progressively diminished. In the children previously vaccinated a pink coloration developed at the site of inoculation, usually attended by the formation of a pustule containing turbid fluid. In the non-vaccinated group there was merely a slight congestion. The authors consider that this method may be of value in determining the degree of immunity possessed by a previously vaccinated subject.

347. Dogs as Leptospira Carriers.

W. KOUWENAAR and J. W. WOLFF (*Nederl. Tijdschr. v. Geneesk.*, January 25th, 1930, p. 376), who publish a preliminary paper on the occurrence of leptospirae in the kidneys of normal dogs, state that it has long been known that leptospirae may occur in dogs. Almost simultaneously with the first appearance of communications on the leptospirae in Weil's disease in men and rats, cases were recorded by German observers in dogs which had died with symptoms of acute jaundice. Since then various investigations have been published on the occurrence of leptospirae in dogs, and it has recently been shown that leptospirae have been found in dogs' kidneys in two clinically different conditions—namely, the Stuttgart dog-plague (canine typhus of Lukes) and infectious jaundice (Okell, Dalling, Pugh). Kouwenaar and Wolff examined 106 healthy dogs for the presence of leptospirae. In 94 their sex and age were noted, 53 being males and 41 females, and their ages ranged from under 1 year to 4 years and over. None of these animals showed at necropsy any naked-eye evidence of disease, particularly jaundice or oedema. The urine was examined in 56 cases, and dark field preparations were always negative. Cultures of liver emulsion in all the animals were also examined without a single positive result. Both kidneys of the 106 dogs were then examined, and though the dark field preparations were always negative, culture of kidney tissue in Vervoort's medium was positive in 6 cases. The strains of leptospira so isolated were not completely identical with the leptospira of Weil's disease. In addition to only a feeble virulence for guinea-pigs, there appeared to be also no serological affinity between the strains from dogs and those from Weil's disease. The object of the present authors has been to draw attention to the occurrence of leptospirae in clinically healthy dogs in a district where relatively numerous cases of human leptospirosis had occurred. The result of further investigations will be published later.

348. Gram-negative Cocci in the Female Genital Tract.

T. CUIZZA (*Ann. di Ostet. e Ginecol.*, February 28th, 1930, p. 158), in common with other observers, has found that Gram-negative cocci other than the gonococcus are sometimes, though infrequently, found in the female genital tract; he alludes to the diagnostic errors, of medico-legal as well as of clinical importance, which may result from confusion of such organisms with Neisser's bacterium. Examining the cervico-vaginal secretion in 65 gynaecological patients, of whom 51 suffered from acute or chronic cervico-vaginal or pelvic inflammation, he found Gram-negative cocci differing from the gonococcus in 6; cultural growth was necessary to establish definitely the fact that these were not gonococci. An organism was grown in pure culture in three cases, and in each had somewhat different morphological and biological characters, which are set forth in detail. In four cases the organism had a diplococcal arrangement. DAVANZO (*Ann. Ital. Ginecol.*, IV, 1929) has isolated from the flora of the cavity of the myomatous uterus two types of Gram-negative diplococci not identical with the gonococcus.

349. The Blood Picture in Varicella.

A. SALVADEI (*La Clinica Pediatrica*, November, 1929, p. 1050) examined the blood in 16 cases of chicken-pox, 5 of which were complicated by pertussis, during the first twenty-four hours of the disease. The ages of the patients ranged from 3 to 5 years. The results were as follows. Both in the pure cases and in those complicated by whooping-cough the eruption of varicella on its first appearance confers an almost specific modification on the blood picture—namely, absolute leucopenia, neutropenia, and relative lymphocytosis, which are almost constantly associated with an increase of the basophils and a diminution of the acidophils.

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

FELAMINE BRAND SANDOZ

SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-

MODEL No. 1.

THE ONLY SUPPORT

Giving direct abdominal uplift

Maintained in any position that the patient may assume without any cramping or binding of the hips whatsoever. The principle is that of a direct anterior-posterior pressure, and enjoys numerous advantages over any other make of support on the market. It is simply fastened by a strap and buckle, and can be adjusted to any degree that the physician may prescribe.

For full particulars apply to:

CLOTHES for DOCTORS

TERMS:
£1 PER MONTH
NO REFERENCES
OR ENQUIRIES

THE old-fashioned method of buying clothes, with its heavy interest charges, is fast becoming obsolete.

Its place is being taken by the new Keith Bradbury system, which is more convenient to customers and certainly more profitable to the tailor.

As so few men make special financial provision for their tailoring needs, delayed payment of accounts for six or twelve months, or perhaps longer, does not help the customer — yet it involves the tailor in considerable interest charges which must eventually be passed on to the customer in the form of overhead expenses.

On the other hand, small periodical payments are hardly missed from one's income, and as a result, the question of clothing becomes a pleasure instead of a bore, apart from which, it enables the tailor to avoid heavy interest dues, which must mean better value for the customer.

Concrete proof of the financial merit of this new system of periodical payments (without references or enquiries) is to be found in the fact that Keith Bradbury Ltd. are able to provide a FREE VALET SERVICE for the care of customers' clothes after purchase, in addition to supplying West End clothing at the low prices quoted in this announcement.

The Ideal Hypnotic and Sedative
". . . . My opinion is that it is the best nervous sedative. . . ." ———, M.B.Cantab.
SCHERING LIMITED, 3, Lloyd's Avenue, London, E.C.3.

DIABETES
Brusson Bread has the lowest starch content of any starch-reduced gluten bread.

Its scientifically graded content of starch, protein, and fat enables the physician to prescribe the correct quantity for each patient. Liberal samples of Brusson bread on request, with copy of "The Amplified Diet in Diabetes," often very useful for handing to patients.

Apply to Superintendent.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

Emol-Kelcet

Samples free to the Medical Profession on request.

FASSETT & JOHNSON, Ltd.

86, Clerkenwell Road, London, E.C.1.

Beneficial in Inflamed and Irritable Conditions of the Skin.

Emol-Kelcet is a natural dusting powder of purely organic origin, combining a marked sedative action with absorbent, emollient and mildly astringent properties. It has a velvety-smooth texture and is remarkably adhesive. Emol-Kelcet allays the itching of Eczema and dries up the exudations of "weeping" cases. It relieves the cutaneous irritation accompanying Measles and Scarlet Fever, and soothes any inflammation which may follow vaccination.

Suppresses putrefaction and bacterial infection of the colon

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State. COATES & COOPER, 41, Great Tower Street, London, E.C.3.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD Co., Michigan, U.S.A.

Also in exactly similar form and price—

SOLID IODINE

A Remarkable advance in the presentation of H_2O_2

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.

Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.

A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 95, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'

in neat, handy glass tubes.

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905).

Local Anæsthesia in Surgical Practice

OPERATION ON BRAIN.

Typical Case.

A. B., aged 42 years.

Diagnosis: Advanced optic neuritis.

Anaesthesia: 60 c.c. of a 6.7 per cent. Novocain-Adrenaline solution.

Operation: A transverse infiltration block was made above the external ear with a vertical line along the proposed line of incision. The skull was opened over an area of 5 × 7 cm. The dura was opened after the ligation of two arterial branches. The opening was covered by the temporal muscle and the skin closed with silkworm gut.

Note.—The patient remarked at the finish of the operation that if this was all there is to such an operation, he would not mind having one every day.

—EXTRACT FROM PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 265, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis-courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent*

PUBLIC HEALTH DEPARTMENT.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Huddersfield invite applications from registered Medical Practitioners for the above appointment.

Candidates should be ladies who are particularly interested in the welfare of mothers and infants, and who are prepared to work wholeheartedly in an intensive scheme for the protection of their health.

Forms of application are not provided.

Candidates should set out their qualifications and experience, and furnish three recent testimonials, and/or two references.

The salary will be at the rate of £500 for the first year, and thereafter at the rate of £600 per annum.

Applications should be addressed to S. G. MOORE, M.D., M.R.C.P., D.P.H., Medical Officer of Health, so as to reach him not later than April 15th.

Town Hall, J. HENRY FIELD,
Huddersfield. Town Clerk.
March 27th, 1930.

Borough of Folkestone.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified gentlemen for the position of Assistant Medical Officer of Health and Port Medical Officer, at a salary of £600 per annum.

The gentleman appointed must possess the qualifications prescribed by the Sanitary Officers Order, 1926, and will be required to devote the whole of his time to the duties of the office. He will also be required to assist in the duties of Medical Inspection of Aliens.

The post is designated under the Local Government and Other Officers Superannuation Act, 1922, and the appointment will be made subject to medical examination.

Applications, stating age, qualifications and experience, accompanied by not more than three recent testimonials, and endorsed "Assistant Medical Officer of Health," should be addressed to me and delivered at my office not later than April 23rd.

There is no special form of application.

Town Clerk's Office, C. F. NICHOLSON,
Folkestone. Town Clerk.
March 31st, 1930.

City of Edinburgh.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Corporation of Edinburgh invite applications from duly qualified persons for the appointment of Medical Officer of Health for the City.

Salary £1,500 per annum, rising by a maximum of £1,750 per annum.

A Memorandum specifying the terms of appointment, and outlining the duties to be performed, may be obtained on application to the subscriber.

Applications, stating age, qualifications, and full particulars of present and past experience, should be lodged with the subscriber not later than April 25th.

City Chambers, A. GRIERSON, S.S.C.,
Edinburgh. Town Clerk.
March 28th, 1930.

Worcestershire County Council.

ASSISTANT COUNTY MEDICAL OFFICER.

The above-mentioned Council invite applications for the post of Assistant County Medical Officer.

Applicants must be registered Medical Practitioners between the ages of 25 and 45, and must possess the Diploma in Public Health.

The duties will include work under the Council's Maternity and Child Welfare Scheme, the medical examination of Elementary and Secondary School Children, and such other Public Health duties as the County Council may direct.

The officer appointed will work under the supervision of the County Medical Officer, and will be required to reside in the district assigned to him or her by the County Council, and to devote the whole of his or her time to the work.

The salary will be £600 per annum, with actual travelling expenses in accordance with the County Council's Scale. The candidate appointed will be required to join the Council's Scheme under the Local Government and Other Officers Superannuation Act, 1922.

The engagement will be subject to three months' notice on either side.

Applications (on forms to be obtained from the County Medical Officer, 29, Foregate Street, Worcester), accompanied by not more than three recent testimonials, must be received by 12 noon on Wednesday, April 23rd, addressed to the County Medical Officer, 29, Foregate St., Worcester.

Canvassing disqualifies, and neither the names of the Members of the County Council nor of the Committee will be supplied.

Shirehall, Worcester. (W.85) — C. H. BIRD, Clerk of the County Council.

West Suffolk County Council.

ASSISTANT COUNTY MEDICAL OFFICER AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for the above whole-time appointment, which includes duties in School Medical Inspection, Maternity and Child Welfare, Tuberculosis, Venereal Diseases, etc., work. Salary £600 per annum if with three years' post-graduate experience; if with less than three years' post-graduate experience £500 for the first year, to be raised to £600 after one year of satisfactory service, plus travelling allowance. Particulars of appointment and forms of application may be obtained from the undersigned, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than April 19th. Canvassing in any form, direct or indirect, will disqualify.

Shire Hall, Bury St. Edmunds, April 4th, 1930. — L. G. H. MUNSEY, Clerk of the County Council.

County Borough of Sunderland.

ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

Applications are invited from fully qualified men and women for the position of Assistant Medical Officer for Maternity and Child Welfare.

Applicants must be registered Medical Practitioners, have had at least three years' experience in Public Health work since qualification, be able to show special experience in Ultra-violet Irradiation treatment, and hold a Diploma in Public Health.

Salary £600 per annum.

The appointment is subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical test as required by the Council for the purpose of that Act.

Applications, stating age, qualifications, and experience in Maternity and Child Welfare work, together with not more than three recent testimonials, should be delivered to the undersigned not later than Monday, April 21st, endorsed "Medical Officer."

Canvassing, directly or indirectly, until after the first selection of candidates, will disqualify.

Town Hall, Sunderland. March 31st, 1930. — H. CRAVEN, Town Clerk.

Burton-on-Trent General INFIRMARY.

HOUSE SURGEON.

The Committee require the services of a duly qualified Second Resident House Surgeon (male).

Salary £150, with board, residence, and laundry.

Duties to commence on May 1st.

Applications, with copies of testimonials, to be sent to the undersigned not later than April 12th.

The Infirmary, Burton-on-Trent. — E. W. THORNLEY, Secretary.

County Council of Durham.

ASSISTANT MEDICAL OFFICER FOR PUBLIC MEDICAL SERVICES.

Applications are invited from registered Medical Practitioners, with experience in private practice, and in Poor Law Institutional and District Medical work, for the post of Assistant Medical Officer for the General Medical Services of the Council.

The scale of salary is £800 per annum, rising by biennial increments of £50 to £1,000 per annum, with travelling expenses and subsistence allowances in addition.

The officer appointed will be required to devote his whole time to the duties of the office under the control and supervision of the County Medical Officer of Health, and to reside in the City of Durham or other approved centre.

The principal duties of the post will be concerned with the Medical Services transferred to the County Council under the Local Government Act, 1929, but the officer will also be required to undertake such other Public Health duties as may be allocated to him.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary; and the appointment will be terminable by three months' notice on either side.

Applications, stating age, qualifications, and experience, and accompanied by copies of not more than three recent testimonials, endorsed "Assistant Medical Officer for Medical Services," must be received by the County Medical Officer, Shire Hall, Durham, not later than April 16th.

Shire Hall, Durham. March 31st, 1930. — HAROLD JEVONS, Clerk of the County Council.

County Borough of Barnsley.

APPOINTMENT OF EAR, NOSE, AND THROAT SPECIALIST.

The Hospitals Committee invite applications for the appointment, subject to the confirmation of the Council, of an Ear, Nose, and Throat Specialist for work in connection with their Isolation Hospitals and School Medical Service at an inclusive salary of £175 per year.

The gentleman appointed will work under the general direction of the Medical Officer of Health, and his duties will consist, as regards the Isolation Hospitals, in (i) routine visits twice weekly, (ii) the performance of any necessary operations, with the exception of tracheotomy, (iii) emergency visits, as required.

As regards the School Medical Service, the duties will be to attend at the School Clinic one hour per week and to treat and advise cases of disease.

Applications, stating experience, etc., should be forwarded before April 12th, to the Medical Officer of Health, 18, Regent Street, Barnsley.

Town Clerk's Office, Barnsley. *March 29th, 1930.* — A. D. MASON, Town Clerk.

Borough of Torquay.

DENTIST.

Applications are invited from persons holding the L.D.S. qualification for the position of Dental Surgeon.

The person appointed will be required to examine and treat the teeth of children attending the elementary schools of the Borough, and the Torquay Grammar School; and also such other cases as may be sent by the Medical Officer from the mothers and children attending the Maternity and Child Welfare Centres.

Salary £500 per annum. The appointment, which will be subject to one month's notice either side, is a full-time one, and private practice will not be allowed.

Application form may be obtained from the Education Secretary, Town Hall, Torquay, by forwarding stamped addressed foolscap envelope.

North Lonsdale Hospital, BARROW-IN-FURNESS.

Applications for HOUSE SURGEONS are invited from fully qualified male Practitioners experienced in the administration of Anæsthetics. Salary £175 per annum, with board, residence, and laundry. Applications, stating age, qualifications, and experience, and accompanied by copies of three recent testimonials, to be sent to the Secretary as soon as possible.

NATURALLY RICH

IN VITAMIN "D"

DEMINERALISED PASTURES

The nutritional value of a milk is intimately dependent on the diet of the cow. Any deficiencies in the diet are reflected in the quality of the milk.

It is now universally acknowledged that of the various factors of nutrition, mineral salts play the most important role. Lime and phosphate deficiencies, which are widely prevalent in many milk producing countries, result in milks poor in these minerals, and in gradual deterioration of the stock which has to be made good by the constant influx of new blood from the herds of this country.

The importance of ample supplies of these essential mineral salts in a milk used for infant feeding requires no stressing. It is futile for a milk to be rich in Vitamin 'D,' whether naturally so or as a result of additions in the shape of irradiated ergosterol, unless the calcium content is adequate.

Milk used in the preparation of Cow & Gate is produced from the rich pastures of Somerset and Dorset where cattle are healthy and sturdy, and have never displayed those symptoms of mineral deficiency which result in "osteophagia" or wanderings to "salt licks" so often met with overseas.

The improved Cow & Gate Roller process carried out in modern hygienic factories, ensures the retention of the calcium and phosphorus salts of the original milk and preserves the balance of natural vitamins required for their assimilation by the infant. For this reason it is unnecessary to add synthetic Vitamin 'D' to Cow & Gate products.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

REGULARITY AND COMPLETENESS OF BOWEL EVACUATION

HOW TO ENSURE BOTH

Attention has recently been drawn to the incompleteness of evacuation common even among those who complacently boast of their regularity.

Completeness, as a distinguished physician said the other day, is "even more important than regularity" in the exercise of this physiological function. Incomplete evacuation doubtless explains why so many people, with regular once-a-day habits, continue to suffer from headache, lassitude, nausea, and all those other symptoms customarily attributed to alimentary toxæmia. The truth is that, in these individuals, the rectal neuro-muscular tension scarcely ever recovers normality.

These discomforts and disabilities can generally be made rapidly to disappear by a minimal, effective dose of Eno's "Fruit Salt," taken each morning before the early cup of tea. Eno is a carefully prepared saline laxative of fine granular consistency, instantly soluble in water with effervescence. It is entirely free from the nauseous and irritating mineral salts. Its pleasant taste and refreshing character are due to its chemical purity and physical texture. Another if its advantages is that it contains no sugar or artificial flavouring agent.

"The Doctor's Emergency Reminder."

The Proprietors of ENO's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

J. C. Eno Ltd., 169, Piccadilly, London, W.1.

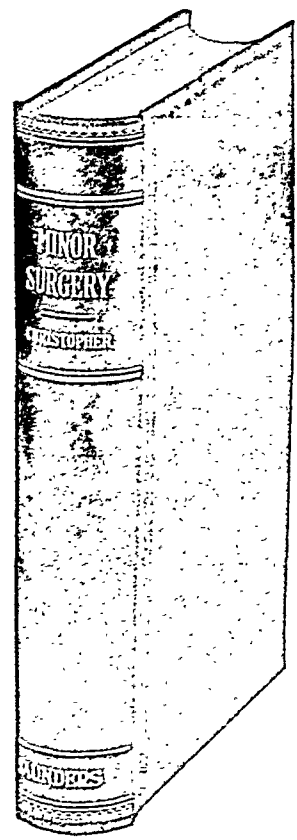
The Issue of the BRITISH MEDICAL JOURNAL is this week 38,500 copies.

"sound advice

NEW BOOK



"superb illustrations

"invaluable"

CHRISTOPHER'S MINOR SURGERY

The LANCET:

"This is a very good book. It arrangement follows the usual lines except for the welcome addition of a long chapter designed for 'The Surgical Intern.' This is full of sound advice which may be read with profit, not only by the house surgeon, but also by his chief, and is mostly applicable to residents in our own hospitals. . . . The book is admirably printed on excellent paper, and the illustrations are superb. The consulting surgeon and the practitioner will find much to interest them, while the house surgeon will find it invaluable."

IRISH JOURNAL OF MEDICAL SCIENCE:

"One is left with a very favourable impression after a perusal of this book. It is well written, quotations are freely taken from authorities on particular branches of surgery, and the illustrations are good. The section on the treatment of boils and carbuncles is elaborately compiled, and is most instructive. A chapter is added on the duties of the hospital surgical intern which contains much sound advice. The author would appear to have taken considerable care in the preparation of the volume, and he is to be congratulated on having produced a book which is the best we have read on minor surgery."

Octavo volume of 694 pages, with over 600 illustrations on 465 figures. By FREDERICK CHRISTOPHER, M.D., F.A.C.S., Associate in Surgery, Northwestern University Medical School, Chicago. With a foreword by Allen B. Kanavel, M.D., F.A.C.S., Professor of Surgery, Northwestern University School. Cloth, 36s. net.

NORRIS and LANDIS'

Diseases of the Chest and the Principles of Physical Diagnosis

The IRISH JOURNAL OF MEDICAL SCIENCE says:

"Norris and Landis on Diseases of the Chest is a work of such outstanding and recognised merit that there is no need to commend its fourth edition to our readers. But perhaps there are still a few physicians who have not realised the peculiar merits of the work; if they are young men just beginning the study of hearts and lungs, and especially if they intend to teach, they will be well advised to buy a copy at once. The reason why Diseases of the Chest is so useful and popular is not hard to find. It is because it is built up on a basis of physics and pathology, and because it is so thoroughly illustrated. . . .

"This fourth edition is an excellent example of careful revision and discreet additions. The book was originally planned and written for the clinician, and subsequent slight alterations have rather enhanced its usefulness for him. It is, we believe, the best book of its kind."

Diseases of the Chest and Physical Diagnosis. By GEORGE W. NORRIS, M.D., Professor of Clinical Medicine at the University of Pennsylvania; and H. R. M. LANDIS, M.D., Sc.D., Director of the Clinical and Sociological Departments of the Henry Phipps Institute, University of Pennsylvania. With a chapter on the *Electrocardiograph in Heart Disease* by EDWARD B. KRUMBHAAR, M.D., Director of Laboratories of the Philadelphia General Hospital. Octavo of 954 pages, with 475 illustrations, some in colour. Cloth, 45s. net.

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta Street, LONDON, W.C.2

LAST DAY for SUBSCRIBERS' PRICE at 17/- net is APRIL 17th.

NEARLY READY. 48th YEAR. *Many Text Illustrations and 61 Plain and Coloured Plates.* **20/-** net, postage 9d.

MEDICAL ANNUAL, 1930

A YEAR-BOOK OF TREATMENT AND PRACTITIONER'S INDEX. A Review of the Year's Progress in Medicine and Surgery, arranged in Alphabetical order.

EDITORS: CAREY F. COOMBS, M.D., F.R.C.P., and A. RENDLE SHORT, M.D., B.S., B.Sc., F.R.C.S.

Physiology of the Central Nervous System and Special Senses

(For the use of Students.)

By N. J. VAZIFDAR, L.M. & S., F.C.S., F.C.P.S.,

Assistant Chemical Analyser to Government of Bombay; Fellow of the Indian Chemical Society; Examiner in Physiology and Examiner in Medical Jurisprudence, College of Physicians and Surgeons, Bombay; Examiner in Chemistry and Examiner in Medical Jurisprudence and Mental Diseases in the University of Bombay.

FIFTH EDITION. WITH THIRTY ILLUSTRATIONS.

EXTRACT FROM REVIEWS OF PREVIOUS EDITION.

A careful compilation, Dr. Vazifdar's book is intended to help students through their intermediate examination and it covers the ground adequately.—*British Medical Journal.*

This is an admirable ab-tract or résumé of a description of the physiology of the Central Nervous System and the Special Senses. The abstract is based upon well-known textbooks of physiology and is accurate and up-to-date in its information.

The author may be congratulated on having produced a book of distinct utility to the Indian students. Being a résumé the book is useful to students and practitioners for revision and reference purposes. There are numerous diagrams and tabular statements which help not only in grasping the facts, but in remembering them. The popularity of the book is well deserved.
—*The Indian Medical Gazette.*

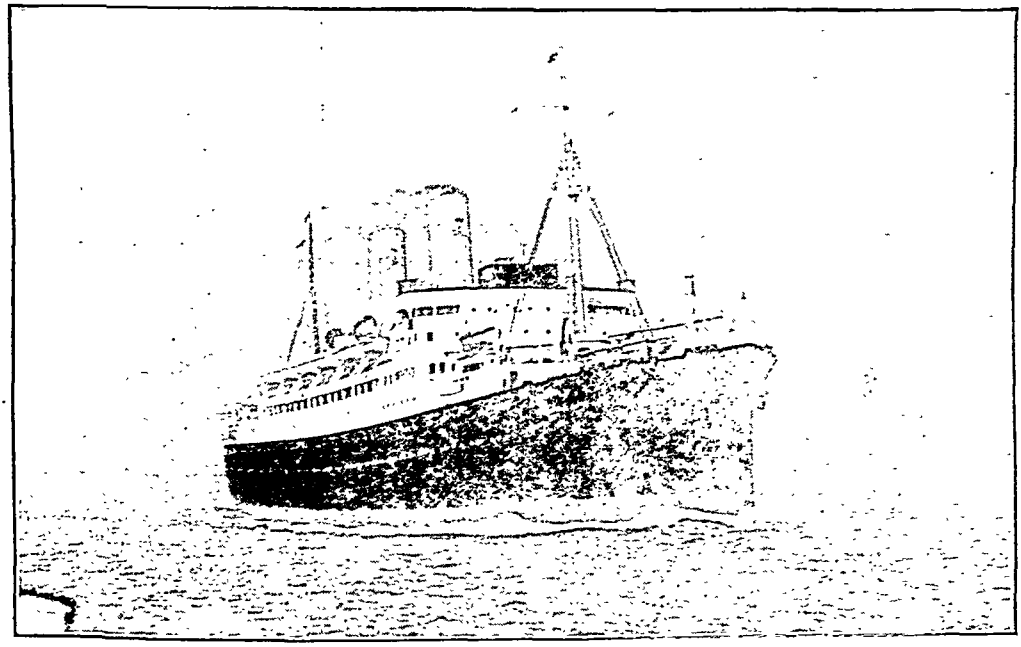
98TH ANNUAL MEETING

OF THE BRITISH MEDICAL ASSOCIATION

WILL BE HELD IN

WINNIPEG, CANADA



AUGUST 26th—29th, 1930.

The British Medical Association and the Canadian Medical Association, in collaboration with the Canadian Pacific Railway and Steamships, have arranged a number of attractive journeys for B.M.A. Officers and Members taking part in the Meeting.

These Official Tours will leave England by

CANADIAN PACIFIC DUCHESS STEAMSHIPS

"DUCHESS OF BEDFORD" AUGUST 8th. | "DUCHESS OF YORK" AUGUST 15th.

A CANADIAN PACIFIC LINER. 20,000 TONS.

All information can be obtained, and Registrations must be made, through the Financial Secretary of the Association at

BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, W.C.1.

A Surgical Support Can Be Effective and Yet Be Light in Weight, Comfortable and Beautiful

Physicians and surgeons themselves, to say nothing of their women patients, demand surgical supports these days which are not only effective but are also light in weight, and comfortable in cut and fit.

Twenty years ago, surgical supports were heavy. Changes in women's habits of life have led gradually to a demand for greater comfort and freedom in surgical supports as well as in "style" corsets. Physicians and Spencer designers co-operating in numerous experiments, know now that a surgical support can be effective and yet be light in weight and pleasant to wear.

Because the Spencer support is individually designed for the patient who is to wear it, it will stay in position on the figure, and do the work required of it, even though it is so comfortable that the wearer is hardly aware of its presence.

SPENCER SUPPORTING CORSET.

Front opened and held back to shew inner supporting section.

Physicians experience but little difficulty in getting the co-operation of patients for whom Spencer supports are prescribed because the garments can be really beautiful, and serve all fashion requirements, and yet do the work that the physician demands of them.

By making an appointment with a Spencer Corsetière you can see and have demonstrated to you all kinds of Spencer supports—those for maternity and post-partum wear, for hernia, enteroptosis, movable kidney, and sacro-iliac strain.

In your own town at any time, you can have the co-operation of a Spencer Corsetière who is trained to take measurements accurately, to describe posture and figure exactly, to adjust garments properly, to give intelligent after-service, under the physician's instructions. We will gladly send you any or all of the booklets on the uses of Spencer supports.

TAKE X-RAYS TO YOUR PATIENT'S BEDSIDE . . .

YOUR patients will be the first to appreciate the convenience of X-rays in their own homes—no longer the irksome, or even dangerous necessity for moving to the nearest X-ray installation—the well-equipped doctor now brings the "Metalix-Portable" with him.

Made ready for use in a minute or two, the "Metalix-Portable" can be used wherever there is electric light. The owner is not called upon to master any technique or intricate mechanism, operation being by means of a simple time-switch. Danger from high tension and stray radiation is non-existent.

The quality of radiograms made with the "Metalix-Portable" is remarkable—ask the doctor who owns one or let us demonstrate in your own consulting room.

Simplicity, combined with accuracy and freedom from danger typify the "Metalix-Portable"—the outfit in use

REGULOL

REGD.

"REGULOL" IS AVAILABLE IN TWO FORMS: "PLAIN" or "COMPOUND." The latter is a combination with Phenolphthalein 4 grains per oz., and is indicated in more acute forms of Constipation where the simple lubricating effect of Paraffin is insufficient.

CUXSON, GERRARD & Co., Ltd.

Oldbury, *Birmingham.*

IT is a highly palatable Emulsion of Liquid Paraffin with Agar-Agar, possessing all the advantages of the former without its objectionable qualities, and forming probably the best possible remedy for Chronic Constipation in Children and Adults.

SAMPLE 1-lb. JAR FREE ON REQUEST.

Please indicate whether Plain or Compound is required.

ASSISTANCE FOR THOSE TREATING SKIN COMPLAINTS

The lessons of the great war added nothing more clearly to the knowledge of the treatment of skin troubles than a realisation of the healing virtues of peat. Used for wounds and for skin diseases, this natural remedy met with the most gratifying success. You can use it conveniently and cheaply if you select from the list of Sphagnol preparations whichever is most suitable for your purpose. There is an ointment, soaps (medical, toilet, and shaving), suppositories, and a lotion. All contain 5, 10, or 15 per cent. of the principle in a medium of the highest quality. All are obtainable from your own chemist.

In order that you can test their efficacy the makers are always glad to send free samples to medical practitioners who write to Peat Products (Sphagnol) Ltd. (Dept. B23), 21, Bush Lane, London, E.C.4.

Samples free to Members of the Medical Profession.

The Treatment of Pulmonary Affections by Inhalation.

THE AËRISER

This instrument converts liquids into a voluminous but almost invisible vapour, or, in the words of the "LANCET," it "renders fluids like smoke," and thus enables medicated vapours to be inhaled continuously without injury to the delicate mucous lining of the air passages.

In all other sprays, atomisers, inhalers, etc., the spray is given off in palpable particles and cannot be used long without giving rise to discomfort. With the Aëriser, however, solutions, whether aqueous, oily, or balsamic, are given off in such a state of fine division that when the vapour is directed on to a sheet of glass or paper it remains unsoiled; consequently, when inhaled the medicament reaches the whole of the respiratory tract even to the innermost recesses of the lungs without causing the slightest irritation.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

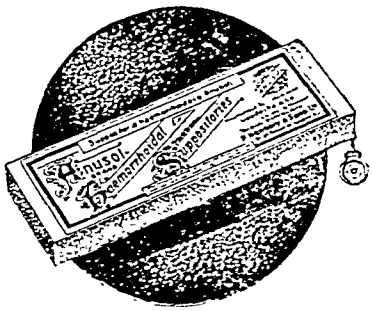
Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

A New Stride Forward in Nose and Throat Therapy

Mistol is a combination of eucalyptol, menthol and camphor in a specially prepared base of petrolatum. It is approved by leading nose and throat specialists for its quick action in relieving irritated and infected mucous membranes.



Due to its oily consistency, Mistol clings tenaciously to mucous membranes, keeping its soothing and astringent ingredients in direct contact with the inflamed parts for a considerable length of time.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER Ltd., Manufacturing Chemists,
184, Queen's Gate. London, S.W.7.

In the Treatment of

Chronic Rheumatism

It has been estimated that approximately 14 per cent. of the total industrial invalidity is due to rheumatic disease, and, further, that chronic rheumatism accounts for more than four-fifths of this figure ("*Lancet*," March 22nd, 1930, p. 607).

The proven value of Contramine—the well-known chemo-therapeutic product—in the treatment of chronic rheumatism is, therefore, of considerable significance. The result of Contramine therapy is distinctly to reduce the incidence of chronic rheumatism, and this drug is recommended now in all the chronic forms of the disease whether of gonococcal origin or not.

Contramine is supplied in ampoules containing a solution ready for intramuscular injection.

Intestinal Disinfection

ALIMENTARY TOXÆMIAS

IN our last advertisement, the subject of Alimentary Toxæmia was briefly discussed, and intestinal disinfection by means of Kerol Capsules was held to be the first line of treatment.

The reason for this may be stated as follows:—None of the ordinary so-called intestinal antiseptics, such as Salol and Beta Naphthol, are found experimentally to exert any disinfection of the contents of the bowel.

On the other hand, the high boiling hydroxyl compounds of the coal tar series are potent germicides, and, being unabsorbed, are non-toxic. They can therefore be administered freely without harm, and are found to prevent the multiplication of the toxæmic intestinal bacteria and to reduce them considerably.

The active principle of Kerol is a complex mixture of these compounds. The administration of two 3-minim capsules thrice daily after meals has been repeatedly shown to reduce the coli content of the stools of individuals taking them by 99 per cent.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

A NEW BLOOD ENRICHING VITAMIN FOOD

SAVORY & MOORE'S SOLUGA

TRADE MARK

SOLUGA is a scientific product prepared under rigid control. It is an Organic Food containing in definite proportions Hormones, Albumins, and Lipoids derived from the Liver, Heart, Brain, Thymus, and Central Nervous System, combined with stable forms of VITAMINS A, B, D, and E, with vegetable proteins, grape sugar, and maltose. In addition, biologically active iron, lime, phosphorus, etc., are present.

INDICATIONS. Generally in all Vitamin deficiency diseases. For Anaemia, in cases of Convalescence. For Neurasthenia, Over-Fatigue, Mental Strain, Nervous Debility, etc. May be prescribed with confidence for Nursing and Expectant Mothers. Assists the development of backward children.

The Analysis of SOLUGA (Dry) shows:

Blood-forming Hormones (extract of calf's liver and red bone marrow	6%
Regenerating Hormones (extract of thymus gland)	2%
Nerve-forming substance (extract of the central nerve system)	2%
Glucose	50%
Galactose	5%
Albumins of high biological value (tryptophane, etc.)	20%
Citrate of Iron	0.4%
Compounds of Calcium, Magnesia, and Silicon	2.7%
Phosphatides	5%

Full particulars and literature sent on application post free.

Supplied in sealed airtight tins. Price 3/- per tin.

Sometimes a major operation...

YOU have many patients in whom coffee-drinking is a habit so consuming and so ingrained that prohibiting it is in the nature of a major operation on the patient's nervous system. Without coffee, their appetite may be diminished, and the temptation to take a cup or two may be well-nigh irresistible.

But now there is a pleasant, sure way to protect your patients from an overdose of caffein without prohibiting coffee . . . good coffee . . . rich coffee . . . satisfying coffee—and that way is to prescribe H.A.G. COFFEE.

And that you may satisfy yourself how fully the effects of caffein have been minimized in H.A.G. Coffee, make the night-test. Send the coupon below for a liberal sample of H.A.G. Coffee. When it arrives, give it this convincing test: drink your first cup of it at night. It won't keep you awake. Next morning you'll know, from actual experience, that patients can enjoy H.A.G. Coffee without fear of caffein effect.

A perfect blend of finest coffees

H.A.G. Coffee is all coffee—nothing but coffee—a delightful blend of the choicest Central and South American coffees. The decaffeinization process takes place before the coffee beans are roasted, leaving undisturbed the spicy flavour, the fragrant aroma—everything that makes coffee "the beloved beverage."

This is scarcely less important than the fact that the effects of caffein have been minimized. For, as you will discover, the delicious flavour of H.A.G. Coffee transforms the order to give up coffee, because of its caffein, from a test of the patient's will-power into a daily delight.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Some observations of the Action of Caffeine," a more complete discussion of H.A.G. Coffee. Send the coupon now.

When vitality is at its lowest and solid food is intolerable—

THESE ESSENCES STIMULATE WITHOUT THE SLIGHTEST STRAIN ON THE DIGESTIVE ORGANS

IN any dangerous illness a condition often arises which makes the taking of solid nourishment impossible. The need then for a form of food which can be absorbed rapidly, without effort, is imperative!

Scores of leading practitioners today find Brand's Essences an ideal preparation in crises of this kind. Out of hundreds of doctors interviewed within the last few months, 99 per cent. said they recommended this product.

Palatable, easy to take, the delicious jelly can be assimilated without the slightest strain on the digestive organs.

For Brand's Essences are powerful exciters of the gastric juices. Hidden in them are those very elements of meat which rouse the secretions of the stomach to digestive action instantly.

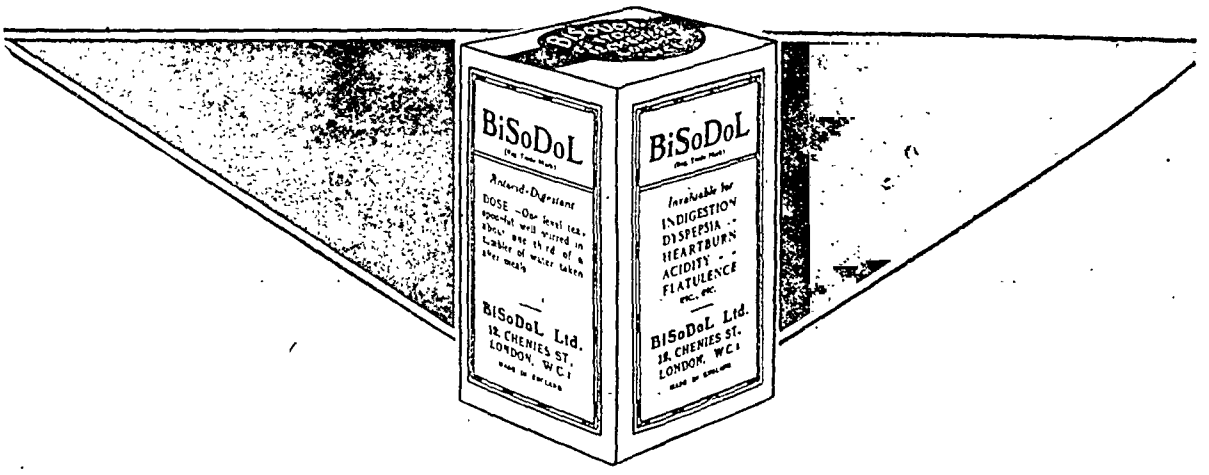
And no substance which could hinder quick assimilation is added. They are simply the pure essence of the finest fresh meat — *conserved in its natural form* without the addition of any colouring, flavouring, or gelatine.

So rapidly can these Essences be absorbed that in states of exhaustion they stimulate and restore vitality almost immediately.

During recovery from illness, they are invaluable in rousing appetite and preparing the patient for more solid diet.

BRAND'S ESSENCES

(Made only from the finest English Beef, Chicken and Mutton)



Brand's Essences are subjected to meticulous laboratory tests to ensure the highest possible standard of quality and purity.

On receipt of a professional card, samples of the Essences will be sent you at once. They are prepared under ideal hygienic conditions, under scientific control, and their purity and proved advantages in illness have made them famous for a century. Brand's Essences are obtainable at chemists and stores throughout the world in tins and glasses. Write Dept. F.2, Brand & Co. Ltd., Mayfair Works, Vauxhall, S.W.8.

Recent investigation shows that the following percentages of Doctors, Dentists, Nursing Homes and Hospitals are recommending Brand's Essences.

DOCTORS	99%
DENTISTS	92%
NURSING HOMES	78%
HOSPITALS	61%

The Alkalies in Respiratory Diseases

Recent work on influenza, the common cold, pneumonia, and catarrhal fevers in general, has served to focus attention on the value of the alkalies in the treatment of these infections. It has been found that a system saturated with alkalies increases the resistance to bacteria. During the influenza epidemic of 1918, patients so alkalinised showed a low mortality rate and, in the main, a quick convalescence.

BiSoDoL, a balanced alkalinising agent, may be effectively employed to combat acidosis and build up the alkali reserve without upsetting the stomach or causing alkalosis.

The utility of BiSoDol as an antacid in hyperchlorhydria, gastritis, gastric and duodenal ulcer, has been abundantly demonstrated. It has also been given with marked success for the control of cyclic vomiting and the morning sickness of pregnancy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

BiSoDoL Limited,
12, Chenies Street, London, W.C.1.

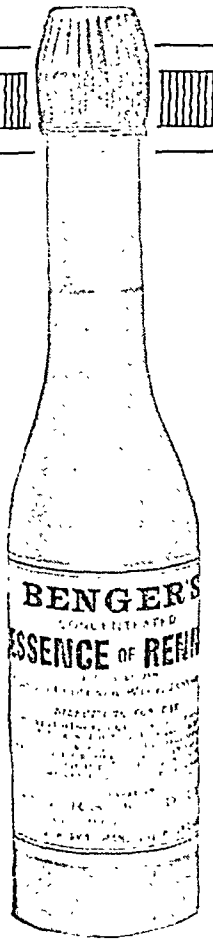
NATURALLY RICH IN VITAMIN "D"

DEMINERALISED PASTURES

The nutritional value of a milk is intimately dependent on the diet of the cow. Any deficiencies in the diet are reflected in the quality of the milk.

It is now universally acknowledged that of the various factors of nutrition, mineral salts play the most important role. Lime and phosphate deficiencies, which are widely prevalent in many milk producing countries, result in milks poor in these minerals, and in gradual deterioration of the stock which has to be made good by the constant influx of new blood from the herds of this country.

The importance of ample supplies of these essential mineral salts in a milk used for infant feeding requires no stressing. It is futile for a milk to be rich in Vitamin 'D,' whether naturally so or as a result of additions in the shape of irradiated ergosterol, unless the calcium content is adequate.



Milk used in the preparation of Cow & Gate is produced from the rich pastures of Somerset and Dorset where cattle are healthy and sturdy, and have never displayed those symptoms of mineral deficiency which result in "osteophagia" or wanderings to "salt licks" so often met with overseas.

The improved Cow & Gate Roller process carried out in modern hygienic factories, ensures the retention of the calcium and phosphorus salts of the original milk and preserves the balance of natural vitamins required for their assimilation by the infant. For this reason it is unnecessary to add synthetic Vitamin 'D' to Cow & Gate products.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

ESSENCE of RENNET
CONCENTRATED (BENGER).
(Curdling Fluid)

Originally prepared at the request of a prominent physician, this highly concentrated essence is of especial value in Infant and Invalid Feeding. As it is concentrated it is much quicker in its effect than most other preparations of Rennet. Whey prepared with Benger's Essence of Rennet is of the greatest value in the treatment of diarrhœa, vomiting, etc.; it can be employed with confidence and will yield good results. Junket can be made more quickly and at a lower cost by using Benger's Essence of Rennet than by any other method.

In 1/- and 1/9 bottles.
Larger sizes for hospitals, etc., use.

LIQUOR PEPTICUS
(BENGER).

"A digestive agent of extraordinary power."
Sir William Roberts, M.D., F.R.S.

Benger's Liquor Pepticus, is a concentrated and highly active fluid pepsin in acid solution which acts particularly upon meat, eggs and other proteid foods.

The best results from the use of Liquor Pepticus are obtained when it is prescribed alone. Should the prescriber wish to combine medicaments of a tonic nature, it will be recollected that those which are free from astringency and alkalinity should be selected.

In 4, 8 and 16-oz. bottles.
Prices: 3/6, 6/6 and 12/6.

The Milk ..... that gives a Perfectly Balanced food for infants

Libby's Evaporated Milk has balanced richness—it is rich in all the food substances of milk and scientifically prepared in such a form that this natural richness is readily assimilable for the building of bone and muscle. The kind of richness in Libby's Milk is the richness that promotes the health of the infant. It will actually ensure better teeth, firmer bones, stronger bodies, and therefore much better health. Sterilization protects Libby's Milk from all contamination up to the very moment it is used. Homogenization breaks up and emulsifies the large fat globules into tiny particles as in human milk.

The whole day's feeding can be prepared at once and will keep fresh and sweet.

Libby's Evaporated Milk

EARLY EGYPTO-BYZANTINE FIGURED TEXTILE MATERIAL WHICH FORMED PART OF A LINEN TUNIC.—Byzantine textiles were widely renowned throughout the Middle Ages, this industry constituting a very large part of the commerce with the west. Early Byzantine textiles were characterised by splendour of colour, harmony and richness of repeated pattern, from which an impression of combined symmetry and dignity resulted. The fabrics were of linen, wool, silk, or sometimes a mixture of these—the designs being inwoven or embroidered. The colours employed in tapestry were purple, violet-brown and red for the background, with designs in violet, indigo, pale blue, yellow, orange, green and blue-black. They were fadeless in a very high degree and were capable of resisting prolonged action of sunlight. It is interesting to notice the influence of Byzantine and Persian textiles upon sculpture and mosaic, in which can frequently be traced motifs which are partly of textile origin. This influence pervades western Romanesque architecture.

VITAMINS A, B & D
HAVE ALWAYS BEEN IN
CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

A Lecture
ON
THE RELATION OF DIET TO HEALTH AND DISEASE.
*SOME RECENT INVESTIGATIONS.**

BY

EDWARD MELLANBY, M.A., M.D.CAMB., F.R.C.P., F.R.S.,

PROFESSOR OF PHARMACOLOGY, UNIVERSITY OF SHEFFIELD.

THERE is but little doubt that some of the most important contributions to medicine in the last few years have come through the study of dietetics and nutrition. Advances in knowledge of these subjects have affected, or ought to have affected, the health of all mankind. I propose, therefore, as one whose lot it has been to be intimately connected with investigations on this subject, to relate something of the work that has been carried out in recent years. The limited time at my disposal only allows of a cursory glance at a few of the problems, but nevertheless I propose to draw attention not only to points which, from a practical aspect, may be regarded as settled, but also to results which suggest that there are other pathological conditions in which it is probable that dietetics will be found to play a dominant part.

What I want to do in this lecture is to give evidence which shows that diet, in addition to supplying material for growth and maintenance of the body and the necessary energy for the performance of its work, also contains two groups of substances—one which tends to produce pathological changes and ill health, and the other which helps the body to protect itself, not only against these toxic factors, but also against other disease-producing agents such as micro-organisms.

I do not propose to discuss the energy-bearing constituents of diet—namely, proteins, fats, and carbohydrates. It is, of course, necessary that the amount of food eaten must contain a certain minimum of energy according to the work performed and heat lost by the individual. It is also true that these energy-bearing substances must include a minimum of biologically available protein both for growth and for maintenance. These are truisms which will always hold, whatever revolutionary discoveries may be made in the future in dietetics.

The history of the relation of food to disease was initiated by two discoveries. One was the work of Eijkman, who proved in 1897[1] that beri-beri was due to the absence from the diet of a substance found in many foods, but especially in the germ of cereals, and known later as the anti-beri-beri, or the antineuritic, vitamin, usually described at the present time as vitamin B_1. The other was the discovery of Holst and Frölich in 1907[2] that fresh foods, especially fruits and vegetables, contained a substance in whose absence from the diet the disease known as scurvy developed. This substance is now known as the anti-scorbutic vitamin, or vitamin C. Both these discoveries—the one which led to the establishment of the etiology of beri-beri, and the other to the etiology of scurvy—have been of great practical significance in themselves, but, for the moment, what I wish to emphasize is that they led to a new angle of thought—namely, that dietetic constituents, present maybe in infinitesimal amounts, are essential to the maintenance of health. Indeed, they led to investigations which ultimately made it clear that many of the commoner diseases of civilized man had a dietetic factor as a basis.

Neither beri-beri nor scurvy is a disease which is commonly found in Africa or Europe. Both are diseases associated with types of restricted diets uncommon in these continents—the one depending upon the consumption of an unbalanced diet of manufactured cereals treated in such a way as to lose the germ and the pericarp of the grain, and the other upon the absence of fresh food, especially of fresh fruit and vegetables. I have, it is true, seen a certain amount of scurvy since coming to Africa, especially in the natives associated with the gold-mining industry, but these cases were few in number, and I think that the medical officers in charge have the disease under control.

As regards beri-beri, I do not think there is much danger of this becoming a practical problem of any magnitude in Africa so long as the staple diet of the natives is whole unprepared maize, although, as I shall explain later, it seems to me likely that this form of dietary may lead to ill health because of certain toxic actions of cereals whose effects can be, and probably often are, prevented by other food constituents.

In order to supply evidence that foods commonly eaten by mankind include both protective and harmful elements, I propose to refer to three practical problems: (1) the condition of the bones and teeth—the susceptibility of the former to rickets and the latter to caries; (2) degenerative changes in the central nervous system; (3) the liability of human beings to infection of the lungs, ears, nasal sinuses, genito-urinary tract, etc. Speaking as an investigator, it is probably superfluous for me to say that the results I shall describe, even when I relate them to disease in human beings, are the outcome of animal experiments. Only by means of such experiments is it possible to track down step by step and ultimately isolate the agent responsible for the phenomenon under investigation. When the results of animal experimentation become clear, it is then possible to test the beneficial effects as deduced on human beings.

DIETETIC FACTORS RESPONSIBLE FOR WELL CALCIFIED AND DEFECTIVELY CALCIFIED BONES AND TEETH.

Work of the last twelve years has cleared up to a surprising degree the factors responsible for well and badly calcified bones and teeth. It may be well to observe, however, that although the practical problem is so far advanced that there is now no excuse for the appearance of rickets or dental hypoplasia in any normal child, there is practically no knowledge as to the intimate mode of action of the specific dietary constituents on the bones and teeth.

By far the most important factor producing well calcified bones and teeth is vitamin D. It seems not unreasonable to say that, no matter what the constituents of the diet—assuming, of course, that they are natural foods—a sufficiency of vitamin D will ensure perfect calcification of bones and teeth. Of course, since these tissues are largely made up of calcium phosphate, it is necessary that there should be some calcium and phosphorus in the food, but the amount can be surprisingly low and yet with an abundance of vitamin D, they will be retained in the body and incorporated in the tissues. On the other hand, if the vitamin D intake is very deficient and the body is not exposed to sunlight, however much calcium and phosphorus there is in the diet, defectively calcified teeth and bones will result. There are occasions, however, when the influence of the calcium and phosphorus intake is of greater importance—for instance when the vitamin D intake is moderate but insufficient in amount. The best example of this is seen when the main dietetic constituent carrying vitamin D is butter, a food containing an irregular but usually comparatively small amount of the vitamin. In this circumstance the addition of calcium salts, either as carbonate or phosphate, results in great improvement of bones and teeth. It would be expected from this statement that the calcifying properties of whole milk would be greater than those of the butter which can be prepared from it. This is certainly the case, partly because a little of the vitamin D is left behind in the separated milk and also because most of the calcium of the milk remains after the separation of the butter.

The relation of vitamin D and calcium and phosphorus intake on calcification can be briefly summarized as follows: (1) When the vitamin D intake is high and the calcium and phosphorus intake low, perfect calcification of bones and teeth will ensue. (2) When the vitamin D intake is moderate, increasing the calcium and phosphorus intake will improve the calcification of bones and teeth. (3) When the vitamin D intake is very low, however high the calcium and phosphorus intake, imperfect calcification of bones and

* Given to the Kenya Branch of the British Medical Association at Nairobi, August 23rd, 1929.

are printed in various black letter types and dated about 1587. They are The Treasure of Pore Men; The Booke of Seynge of Waters; the Myrrour or Glasse of Helth; The Widdowes Treasure; Directions for Health both Naturall and Artificiall, by William Vaughiam; and a Booke of the Properties of Herbes, which is called an Herbal. The Treasure of Pore Men and the Widdowes Treasure give advice in treating various ailments, on cooking, fruit preserving, etc., much as the modern *Enquire Within* does. The Booke of Seynge of Waters deals entirely with urine and its appearances and their significance in diagnosis. It is very like a printed form of the Henry VII manuscript, and with the same illustrations. The Herbal is the only known copy of this tract. It is black letter, and has a small, crude, two by one inch wood engraving on the title-page of the heads of two men, labelled Amos and Job, and on the last page a circular cut of St. John the Baptist. There is no date to it, and no mention of its author. The Myrrour or Glasse of Helth necessary and needful for every person to loke in that will keep their body from the sekeness of the Pestylence, is astrological, and is by Thomas Moulton, Doctoure of Dyvynytie, of the Order of Friars of St. Augustine. It shows the borderland between mediaeval astrology and modern medicine, and one page especially attracts attention. We all know that Shakespeare derived part of his account of Cleopatra on her barge word for word from Plutarch. For his seven ages he evidently put in his own words the astrological lore on the subject.

A book which will appeal to the general reader is one by John Parkinson, apothecary and "herbarist" (1629). Parkinson was apothecary to James I, and later Charles I gave him the grandiose title of "Botanicus Regius Primarius." In it he described one thousand plants, and illustrates seven hundred of them, in what is said to be "the first book which separately described and figured the subjects of the floral garden." The short title of the book is "Paradisi in sole, Paradisus Terrestris"; its long title runs on: "or a garden of all sorts of pleasant flowers which our English ayre will permitt to be noursed up, with a kitchen garden of all manner of herbes; rootes, and fruites, for meate or sause, used with us, and an orchard of all sorte of fruit-bearing trees and shrubbes fit for our land, together with the right ordering, planting and preserving of them and their uses and virtues." It requires but a small knowledge of Latin to see that part of the short title is a pun on Parkinson's name—"The Earthly Paradise of Park-in-sun." The late Mrs. Juliana Horatia Ewing was, she said, "so bewitched by the quaint charm of the book" that she wrote a story with the title of *Mary's Meadow* (1884), proposing in it the "Game of the Earthly Paradise," which was to beautify hedges and bare places by planting wild flowers. The book led to the formation of a Parkinson Society with similar objects. *Mary's Meadow* tells of a family of children who had adopted the objects of the society, and as a story of children's ways can be read with delight to-day.

Another old book (1596) of special local interest, because it is the first medical book written by a Manchester practitioner, is one by Thomas Cogan (1545–1607), an Oxford graduate in arts and physicke. He was in 1575 appointed high master to the Manchester Grammar School, but he was also allowed to practise as a physician in the town, probably because of the poor stipend attached to his scholastic duties. He died in 1607, leaving behind him "the character of an able physician, a Latinist, a good neighbour and an honest man."

The book is called "The Haven of Health," and its fuller title-page (they were very explanatory in the early days of printing) says that it was "chiefly made for the comfort of students and consequently for all those that have a care of their health. Amplified upon five words by Hippocrates —Labour, meat, drink, sleep, and Venus." In it he gives advice on how to keep well, with much information about the values of various foods, and referring pointedly to those peculiar to Lancashire, which differed from his Oxonian dietary. His advice is fortified by many quotations from the Bible and previous writers. He was a well-to-do man, and left 4d. apiece to every boy in the school at the time of his death.

England and Wales.

The London County Council and Post-Graduate Medical Education.

A REPORT was laid before the London County Council at its meeting on May 27th with regard to the "scheme of post-graduate medical education centred in London," as recommended by the committee appointed by the late Minister of Health (see *British Medical Journal*, April 19th, p. 745). It is pointed out that the Council's hospital in Ducane Road, Hammersmith, in association with which it is proposed to construct the new medical school, was the subject of consideration by the Council a year ago, when certain proposals for additional accommodation for the acute sick and for the nursing staff were held in abeyance pending the issue of the Post-Graduate Committee's report. The conversion of the Hammersmith Hospital for the purpose of the proposed British Post-Graduate Hospital and Medical School would involve arrangements for the provision elsewhere than at that hospital of the additional accommodation, urgently needed in West London, for the acute sick. The London County Council is also left in some doubt regarding the finance of the proposals. The estimate of maintenance cost of patients given in the report of the Post-Graduate Committee indicates that an annual upkeep cost of about £250 per bed per year is contemplated, as against the present cost of about £137. It further appears that whereas the Government's financial liability is definite, that of the Council would be undefined. The Central Public Health Committee of the Council feels strongly that, while the Council should co-operate with the Government in the scheme, and should appoint representatives, on the invitation of the Minister, to serve on the committee to be set up for proceeding with the necessary action in the planning and construction of the medical school, it should not be committed to the principles of the scheme until it has had a full opportunity of considering the result of the deliberations of this committee. The Finance Committee also is unwilling to accept an undefined liability, and states that it has learned with surprise that at an interview with the secretary to the Ministry it was assumed that the Council's acceptance of the Minister's invitation to appoint representatives to the committee would involve acceptance beforehand of the basis of the partnership. It is held that it should be open to the committee, if it thought fit after exploring the finances of the scheme, to propose a redistribution of the financial responsibilities contemplated by the Government when it undertook to give to the scheme financial support.

Medical Women's Federation.

The thirteenth annual meeting of the Medical Women's Federation was held on May 8th, at the Medical Institute, Newcastle-on-Tyne. The annual report showed progress in the work of various departments. In presenting the financial statement the honorary treasurer stated that the loan funds continued to be of great assistance to young practitioners. At the meeting of the council in the College of Medicine on the following day, Miss Louisa Martindale, M.D., was elected president in succession to Dr. Catherine Chisholm. Among the subjects discussed at the meeting was the position of married medical women on the Birmingham Hospital staff, and the proposal to exclude them from continuing hospital work after marriage. The hope was expressed that the governors would reconsider the resolution. Permission was given to the London Association to publish the conclusions of its Menstruation Committee, which has completed an investigation of 6,000 cases. A new association was reported to have been formed by the medical women in Oxford and surrounding district. At a dinner given to the members of the Federation by the North-Eastern Association Dr. Ethel Williams, president of the local association, remarked that the Federation had increased its membership from about 400 to 1,314 since it held its first meeting in the provinces in 1919. She thanked the past presidents, four of whom were present, for the work the Federation had done on behalf of medical women. Replying to the toast

of "The Medical Women's Federation and President-elect," Miss Martindale gave an interesting account of the origin and work of the Cancer Research Committee of the London Association, which had culminated in the establishment of the Marie Curie Hospital for the treatment of cancer by radium. She emphasized the importance of team work in medicine, and outlined the scheme under which research is carried out in the new hospital. In commenting on the value of the Federation to its members Miss Martindale said that through its representatives on the Medical Women's International Association the Federation was a link with the medical women in over forty other countries. The dinner was followed by a reception in Armstrong College.

Leicester Royal Infirmary.

The contention that voluntary contributions from motor owners are not commensurate with the costs incurred by voluntary hospitals in the treatment of motor and traffic accidents is supported by the governors of the Leicester Royal Infirmary and Children's Hospital in the 157th annual report for 1929. During the year 1,373 persons, injured in traffic accidents, were treated by the infirmary, and 326 were admitted to the wards. The approximate cost of treatment in the hospital is stated to have increased from £1,831 to £3,266. The governors express the hope that the Road Traffic Bill, now before Parliament, will incorporate a clause providing for the adequate compensation of hospitals by insurance companies accepting third party risks. (This clause, which proposes a payment up to £25 for the treatment of each person, has been retained by the House of Lords. A report of the discussion was published in the *British Medical Journal* of April 26th, p. 802.) The general work of the infirmary continues to develop in all departments. Towards the end of the year the reconstructed central wing, which contains 105 beds, was opened by the Duchess of Rutland. This wing will relieve the acute pressure on the temporary accommodation, which has been taxed by an increase in the number of in-patients from 7,380 to 7,447. Valuable assistance in dealing with this problem was given by the various convalescent homes which co-operate with the infirmary in the treatment of patients both before and during convalescence. More than a thousand patients were transferred to those homes during the year by arrangement with the St. John Ambulance Association. By taking full advantage of these facilities a waiting list of 400 patients is expected to be gradually reduced. Two new operating theatres were opened at the beginning of the year. Over £4,500 has been expended in the purchase of radium, and further purchases are contemplated when funds permit. The total expenditure for the year was £86,364. Subscriptions and donations increased by small amounts, and generous benefactions were received for the endowment of cots and beds. The financial statement, which shows a deficit of £764, is regarded as satisfactory.

Society for Relief of Widows and Orphans of Medical Men.

The annual general meeting of this society was held on May 21st, with Mr. V. Warren Low, C.B., F.R.C.S., president, in the chair. It was reported that £5,252 had been distributed during 1929 among the widows and orphans in receipt of grants, and the invested funds of the society now amount to £140,700. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. Membership is, however, retained, provided the by-laws are complied with when the member moves anywhere outside this area. Relief is only granted to the widows and orphans of deceased members. The annual subscription is very small compared with the benefits that may be derived. The annual subscription is £2 2s. for a member who at the time of his election is not over 40; £3 3s. if between 40 and 50, and £4 4s. if over 50 years of age. The great advantages that may be gained for a member's widow or orphans are illustrated by the following figures: during 1929 four widows died; one had been on the funds since 1904 and received in grants £2,200—her husband had paid in subscriptions £31 10s.; another came on the funds in 1918 and received £750; another who came on the funds in 1915 received £1,050; and the last widow who died came on the funds in 1925 and received grants amounting to £300. The directors would like to bring to the notice of the newly qualified and also the newly married members of the profession this society, which is one of the oldest of its kind, having been founded in 1788 and incorporated by Royal Charter in 1864. All particulars and application forms for membership may be obtained from the secretary at the offices, 11, Chandos Street, Cavendish Square, W.1.

Middlesex Hospital Club.

The Middlesex Hospital Club, which is composed of old students of the medical school, held its annual meeting last week. The club was founded many years ago with the idea of arranging a periodical reunion. An annual subscription is paid by the members with a view to building up a fund which can be used to relieve old Middlesex men in distressed circumstances or to assist in any scheme for the benefit of the hospital or medical school. From time to time large contributions have been made to the hospital funds, notably in times of crisis, and at the beginning of the first appeal for rebuilding a substantial sum was voted to the reconstruction fund. At the last annual meeting a further sum of £250 was voted on condition that the hospital board agreed to allot space in one of the basements for a squash racquets court for the resident officers. Most of the members of the club have held house appointments and realize how important it is for some provision to be made for the resident staff to get active exercise. House-physicians and house-surgeons are often unable to leave the hospital premises for several days on end. The board has gladly accepted the gift and agreed to the conversion of the space chosen for this purpose, the cost being met by a contribution from the club. The rebuilding of the hospital has now reached a critical stage. The next step will be to demolish the condemned east wing and cross-piece preparatory to their re-erection. The splendid new west wing gives some idea of what the completed building will be like. A final effort is necessary in order to ensure the completion of the scheme.

Ireland.

Reports of the Rotunda Hospital.

THE reports of the Rotunda Hospital for the year ended October 31st, 1929, deal with 2,382 patients treated in the wards of the hospital, of whom 2,034 were delivered, and with 2,045, of whom 1,805 were delivered, attended in their own homes. The results of the year's work are set out in a series of thirty-seven tables, from which the following facts of outstanding interest are taken. Among the 2,034 women delivered in hospital, 521 had albuminuria, nearly 28 per cent. There were no maternal deaths in this series, but 60 of the infants were stillborn. Nine of the women had eclampsia, and of these one died. In all the cases the routine Rotunda treatment was persisted in, except that glucose was given in quantity both under the breast and by the bowel. Accidental haemorrhage occurred in 43 cases, of which 2 were fatal. The patients grouped under this heading included 25 who were toxaemic, 5 or 6 of these having recurrent toxaemia, and 18 with true accidental haemorrhage. No deaths occurred among 13 patients with placenta praevia, but only 2 of the infants were born alive, both at term. The treatment in 108 cases of disproportion was as follows: forceps delivery in 27, version and delivery in 7, Caesarean section in 35, and destructive operation in 5; the remaining 34 went on to spontaneous delivery. Marked uterine inertia occurred in 37 cases; one of these cases was treated by Caesarean hysterectomy, two by Caesarean section, and nearly all the others were delivered by forceps. Three spontaneous births occurred in this series. Caesarean operations were performed in 18 women for the first time, this series including two cases in which Caesarean hysterectomy was performed, and in 18 other patients Caesarean section was repeated. There was no mortality with Caesarean section. Forceps were applied in 138 cases, a rate of 6.7 per cent.; there were

seven stillborn babies in this series, but no maternal deaths. In commenting on these figures the Master suggests that though every effort should be made to keep down the number of forceps deliveries, this caution must not be carried to excess, for if it is babies will be allowed to die *in utero*. Labour was induced in 116 cases, in 57—all successful—by the oil-quinine method. Bougies were used in 44 cases, with 3 failures, puncture of the membrane in 10 cases with 1 failure, and seat-angle tests in 19 cases. The morbidity rate according to the B.M.A. standard was 2.5 per cent.; it has never before been below 3, but the Master is inclined to the view that with the large number of difficult cases referred to the hospital without any antenatal care this level cannot be sustained. During the year 10 deaths took place in the hospital and 2 in the extern department, and as the total deliveries in both departments amounted to 3,839 the percentage mortality was 0.31.

Handy-women as Midwives.

At the annual meeting of the Irish Nurses' Union the following resolution was passed: "That, in view of the very grave consequences which have lately occurred in maternity cases, where unqualified women were acting in the capacity of midwife, we call upon all supervising authorities to take action against the so-called handy-woman." Dr. T. Hennessy, Irish Medical Secretary, said that the employment of handy-women was causing justifiable indignation among the nursing profession. Doctors should never act with unqualified midwives, for in doing so they were endangering the life of the patient, for whose benefit the midwifery laws had been framed. It occasionally happened that a doctor worked with an untrained nurse because the trained nurse available was unfriendly to him. He thought that doctors and nurses were equally responsible for the position complained of. If the nurses did not report such cases he did not know who was to do it. Qualified nurses who did not report matters of this kind were as much offenders as the handy-women. The qualified nurse who was also a midwife, and who attended a midwifery case after an infectious case, was also an offender, and should be made amenable to the law. Dr. Bethel Solomons, Master of the Rotunda Hospital, expressed surprise that his views had been sought about the handy-woman, who, he thought, had long ago died the death she deserved. He would certainly do all in his power to prevent anyone working with handy-women, especially at a time when so many nurses were looking for work. He was warmly in favour of a scheme for the inspection and registration of nursing homes—general and maternity.

Modern Science.

In a recent public address Dr. Robert Davitt of Jervis Street Hospital said that modern medicine dawned about the beginning of the sixteenth century, mainly as the result of the pioneer anatomical work of Leonardo da Vinci and Andreas Vesalius. From that time there had been a steady advance of the greatest importance in linking up modern medicine with the special sciences. The physician was as much a specialist as the surgeon or the radiologist, or the specialist in this or that region of the body, but his field was wider and more varied and difficult than that of his colleagues if it was tilled to its fullest and not merely used for superficial grazing. Physiologists had brought chemistry more and more to their aid, with the result that a new subscience had been found—namely, biochemistry, or the chemistry of living tissues. *X* rays had added greatly to their knowledge of many conditions; the physicist had come to their aid with the introduction of the electro-cardiograph, an electrical apparatus which had proved of immense value in the study of diseases of the heart, and had enabled important advances to be made in many other directions. Diabetes could now be controlled, and often cured, by insulin; pernicious anaemia, until lately considered invariably fatal, was now amenable to treatment by liver feeding; syphilis, which used to outrival leprosy in its hideous effects, could now be cured completely if the patient saw a practitioner in time; leprosy itself was gradually being brought under therapeutic control; cancer still reared its ugly head undaunted, but tuberculosis, though still active, had lost ground greatly during the last half-century, and would lose, it was hoped, still more in the future. Dealing with preventive medicine, Dr. Davitt said that it had a great many achievements to its credit, as was shown by the enormous decrease in the number of epidemics. Twenty-five years ago it was not uncommon to find an average of ten to fifteen cases of typhoid in any Dublin hospital at any given time. Now it was rare to have more than one or two in the year. Recent advances in knowledge had resulted in more detailed investigation of the different ills that flesh was heir to, and, consequently, in a big addition to the diagnostic armamentarium of the up-to-date clinical hospital. It followed that the cost of properly equipping a hospital was far greater than it used to be, a fact of which the public were perhaps unaware. It might be asked if the modern trend of medicine had been of great benefit to the patient, or if it had militated in any way against him. Over-specialization in the branches of any one pursuit often tended to result in disarticulation of the whole. In the big foreign cities, with their heavily endowed hospitals and medical schools, specialization was carried out to such a degree that, as far as the patient was concerned, it might be a disadvantage. A man entered the ward of the hospital; he was promptly examined by the cardiologist; then the gastro-enterologist took him in hand; then the neurologist examined his nervous system, the laryngologist his nose and throat, and so on. At the end of a week or so there was a sheaf of reports on his chart, but the unfortunate man had nobody attending him whom he really could call his doctor. In Dublin they were undoubtedly behind some other cities in clinical research work, owing chiefly to lack of facilities caused by shortage of money, but it could safely be said that more consideration was paid to the human side of the relation between patient and doctor than in most other countries. At the same time, said Dr. Davitt, the Dublin hospitals had been brought up to date, and would, he hoped, continue to keep so. If they could make use of modern methods and equipment, and at the same time maintain their old tradition of looking on the patient as a human being, Dublin would have every reason to be proud of its hospitals. Dr. Henry Stokes, in proposing a vote of thanks, said that many cases in hospital required five, six, or seven departments to investigate them, and as all of these departments required to be paid there was not money enough to go round. Nevertheless medical and surgical science in Dublin was holding its own. There was no doubt that in the long run the bedside physician was the man whom the patient liked best.

Scotland.

Royal Victoria Hospital Tuberculosis Trust.

ATTENTION is drawn in the annual report of the Royal Victoria Hospital Tuberculosis Trust for the year ending June 30th, 1929, to the continued increase in applications for the admission of children to the Southfield Sanatorium Colony. The number of children in residence continues to rise far above the proportion which was intended in the original scheme, and throughout the year under review the nursery population constituted 50 per cent. of the whole. This growing demand, and the hopefulness of the clinical outlook in childhood, have led the committee to consider the extension of facilities for the treatment of tuberculosis at this early stage, particularly in view of the fact that it is possible by skilled treatment and a process of detuberculinization to immunize the child in some degree against further infection. It is hoped that by extending still further the field of observation at the Sanatorium Colony proof may be obtained of the validity of the principle of anticipatory detuberculinization. Reference is made in the report to the favourable progress of the general campaign against tuberculosis. In Scotland not only has the decrease in mortality due to this cause continued, but in recent times there has been an acceleration in its rate, and this decline has been notably greater than that attributable to all other causes. Various lines of research work have been undertaken or continued during the year under review. In collaboration with the bacteriological laboratory

of the University of Edinburgh, and the research laboratory of the Royal College of Physicians, an attempt has been made in the laboratory at Southfield to standardize tuberculin satisfactorily. The method has now been perfected, and it is being used regularly for standardizing the tuberculins prepared at the laboratory of the Royal College of Physicians for distribution throughout the country. Attention has also been directed to the blood changes in tuberculosis. The sedimentation test has been widely applied, but although in some cases satisfactory information was obtained, in others the evidence proved to be faulty and even misleading. The value of the differential leucocyte count seemed to be definite, and repeated examinations are recommended in order to assist prognosis and to guide treatment. Certain new alleged remedies for tuberculosis have also been tested. The experience of the Southfield Colony and the various tuberculosis institutions linked with the Trust has indicated that the supposed immunity conferred by glandular tuberculosis is accidental or even fanciful. An investigation is in progress to determine the degree to which cattle may be infected with tuberculosis by man, and the channels and character of the resulting infection. An appeal is made in the report for a more generous support of the research work of the Tuberculosis Trust; the committee believes that immense progress could be made if, for the next five years, it could receive an additional sum of £600 annually for this purpose. The Colony is, moreover, an educational centre for undergraduates, post-graduates, and nurses. There is close co-operation between the Tuberculosis Trust and the National Association for the Prevention of Tuberculosis as regards educating the lay public. One of the four medical commissioners, Dr. Harley Williams, appointed by the National Association, has been working entirely in Scotland, lecturing with cinematograph films and lantern slides. Nearly 400 meetings have been held, and his work has been particularly valuable in the Highlands and Islands, where he has been able to tour by motor car through otherwise inaccessible regions. The Tuberculosis Trust gives help in cases of economic difficulty associated with tuberculosis, and an appeal is made for further financial support in this connexion.

Astley Ainslie Institution.

The Lord High Commissioner to the General Assembly, Mr. James Brown, M.P., on May 22nd performed the opening ceremony of the extended Astley Ainslie Institution at Grange Loan, Edinburgh. Mr. Andrew Henderson, chairman of the governors, presided, and said that the institution had been founded and endowed through a bequest by Mr. David Ainslie of Costerton in 1900. He had left directions that the residue of his estate should be allowed to accumulate for fifteen years; the sum available had amounted to close upon £1,000,000. The institution was intended for the relief of convalescents from the Royal Infirmary of Edinburgh; the name Astley referred to Mr. Ainslie's nephew and heir, John Astley Ainslie, who had predeceased him. The governors had decided that the institution should deal with patients suffering from curable conditions, who had definitely passed the crisis of their illness, and who might reasonably be expected to regain normal health. The work of the institution would also include scientific investigation of the processes involved in the gradual restoration of health, which constituted convalescence. It was an interesting fact that the site formed at one time a part of the boroughmuir on which had stood the ancient chapel of St. Roque. Victims of the plague were isolated there in the sixteenth century. Its buildings also included the property of Millbank, formerly the home of James Syme, in the drawing room of which Joseph Lister was married to Syme's daughter in 1856. The chairman said that this room would be preserved in its original state. At the present time 120 patients were in residence, but the completed institution would provide for the accommodation of 150 patients. The grounds extended to about thirty-one acres, and embraced four mansion houses as well as a small private golf course. In addition to these old mansion houses which have been reconditioned as hospital blocks and an administrative department, two large pavilions of one story on a butterfly plan with wide verandahs for open-air treatment have been erected. The new buildings also include a kitchen department, nurses' home, and scientific department. The Lord High Commissioner was presented with a key for the purpose of opening the new scientific department; before doing so he remarked that the institution was well equipped in every way. He was glad to know that research work was being undertaken, and he hoped that from such a well-equipped institution much important information would be obtained. He hoped that similar institutions would be established in other parts of the country.

Commissioner's Visits to Edinburgh Hospitals.

In accordance with the annual practice, the Lord High Commissioner, accompanied by Mrs. Brown, paid ceremonial visits to the various medical and other institutions in Edinburgh. On May 21st a visit was paid to the Royal Infirmary, when prizes were presented to the nurses who had been successful in recent competitions. The party subsequently paid an hour's visit to one medical and two surgical wards and chatted with the patients and nurses. A visit was also paid to Newington House, the home of the Scottish National Institute for blinded sailors and soldiers. Here the Commissioner was received by the Rev. Thomas Burns, chairman of the board of management, and praised the courage of the men in overcoming the disabilities that had been caused by wounds or disease. He also congratulated them upon the neatness of the work they had learned to do in basket making, mat making, boot repairing, and leather work. A visit was also paid to the neighbouring home for blind women. At the Edinburgh Foot Clinic, where Their Graces were received by Bailie Peter Given, the Commissioner remarked that the work done was of such importance that it should be classed along with all other medical work.

Correspondence.

BRUCELLA ABORTUS INFECTION.

SIR,—In view of the attention now being directed to undulant fever I should like to record a case I have been attending for the past six weeks.

The patient, a lady of 60, is athletic, and has always enjoyed excellent health. She has lived in this country, except when she visited Baghdad in 1922, Zululand in 1925, and California in 1922. She first consulted me on April 3rd, giving a history of vertigo, nausea, and furred tongue since March 22nd, with a chill on March 26th while yacht sailing on a cold day. She complained of sleeplessness, lassitude, headache, and pain over the liver region. The tongue was thickly furred, and the liver was enlarged; there was some tenderness over the appendix region, and stiffness of the neck. The temperature was 102° F. and the pulse rate 80. The heart and lungs were normal. The urine contained a small amount of albumin. The patient had a good deal of flatulence, and her bowels were loose, with unpleasant motions about twice daily.

From this date treatment was symptomatic, with a moderately light diet, a daily bath, and gentle massage for the liver and neck. On April 10th, as the condition did not improve, a sample of blood was sent to the Virol Research Laboratories for investigation of the agglutination reaction against typhoid, paratyphoid, and *Br. abortus*, and they reported as follows: "The blood serum tested macroscopically for agglutination is negative to *B. typhosus* (both H and O), *B. paratyphosus* A, *B. paratyphosus* B, *B. paratyphosus* C, each in a dilution of 1 in 50 upwards. The serum, however, gives marked agglutination of *Br. abortus* and *Br. melitensis*, the titre against the former being 1 in 3,200, and against *Br. melitensis* 1 in 1,600. The case is almost certainly one of *Br. abortus* infection."

As the liver had diminished in size, massage was stopped, as well as all medicines, and salol grs. v was now given three times daily. On April 20th the patient was still taking her daily bath, and the sweating, which was rather a marked feature at the beginning of the illness, was less. The bowels were still open about twice daily, but the motions were less offensive. There was slight tenderness over the gall-bladder; the spleen was now easily felt; the pulse missed beats occasionally, but its rate was still not higher than 80 per minute.

On April 26th the patient's general condition was exceedingly good. The pulse was still slow; the tongue was only slightly furred and moist; the patient's appetite was good, but she complained of flatulence; otherwise she had no symptoms of indigestion. On May 7th a further sample of blood was examined,

and reported on as follows: "Serum agglutinates *Br. abortus* 1 in 5,000 and *Br. melitensis* 1 in 2,500 (Oxford standard emulsions)."

On May 14th the temperature was again rather higher. The patient had been sweating, had had "internal shiverings," and was more wakeful at night. The tongue was again more furred, and the patient had a nasty taste in the mouth. There was no tenderness in the abdomen, except over the gall-bladder; the spleen was still palpable; the lungs were normal; the pulse rate was 80 and missing beats.

No conclusion has been reached as to how the infection was conveyed. The patient lives in the country in ideal conditions. She does not drink raw milk, but comes in contact to some extent with animals on her home farm, where there are three cows only, and these give a negative reaction to the agglutination test for Bang's bacillus. There are seven pigs, six sows, and one boar, and their young. One only has been tested, and this gives a positive agglutination with Bang's bacillus. On three neighbouring farms there have recently been abortions among the cattle. Further epidemiological inquiries are being made.—I am, etc.,

Cowes, May 18th. ARTHUR E. HAY.

STERILITY IN WOMAN.

SIR,—Perhaps Mr. Kenneth Walker would have understood my attitude towards the routine examination of semen in cases where the wife seeks advice on account of sterility if I had expressed myself more clearly. My attitude is somewhat that of Mr. Leith Murray, who writes (May 24th, p. 978) that, though it is a scientific and humane step, he has ceased to insist on it, though endeavouring to do it in private cases. Mr. Kenneth Walker condemns my attitute as retrograde, implying, I take it, that the routine examination of the semen is an advance in medicine, though it would be hard to define how medicine is advanced by a method of examination which has no practical beneficial results whatever except this, that in those cases where examination of the wife discloses no reason for the sterility she is spared the inconvenience of a dilatation of the cervix (though Mr. Walker, for some reason, would include a curetting). I do not deny, of course, that an advance has been made in the sense that we now know that in about 20 per cent. of cases the man is at fault; but the utilization of this advance by insisting on the application of the test in all cases indiscriminately may be scientific (in the narrow sense of the word), but it generally useless and may be harmful. The course I advocate is briefly as follows: that in all cases with a pelvic lesion, especially acute anteflexion and dysmenorrhoea, treatment should be advised; in cases where no abnormal physical signs can be found the wife should be told that a dilatation may increase the possibilities of conception taking place, but that a complete examination should include a test of the husband's fertility, and that the test can be carried out if they wish it. It is not humane or useful, even if it is scientific, to destroy hope or to risk humilation of some "poor over-sensitive" husband by insisting on the examination in all cases.—I am, etc.,

Leicester, May 24th. T. C. CLARE.

BIRTH CONTROL AND THE MEDICAL PROFESSION.

SIR,—In a recent debate in the House of Commons on maternity and child welfare, Dr. Vernon Davies, the Conservative member for Roxton, is quoted in the *Times* as having made the remarkable statement that "all competent medical authority was overwhelmingly opposed to birth control. . . . He quoted the authority of gynaecologists and obstetric physicians. . . . They were the people competent to judge and, almost without exception, they held that birth control was detrimental to the woman and to the child."

Such pronouncements are bound unduly to influence public opinion when made by a member of the medical profession. This being so, it is surely time that members of the medical profession should cease to make such rash statements, and should weigh this matter from a scientific standpoint unbiased by any personal, ethical, or sociological considerations. The public is obviously dependent upon doctors for guidance in the hygienic aspects of this question, and any public utterances emanating from doctors should be supported by reliable statistics based on scientific investigation.

It would be interesting to know on what authoritative information Dr. Davies is able to make his statements, and also the names of the gynaecologists and obstetric physicians who supplied it, since there is every indication that the leading members of this branch of the profession have been unable to convince themselves that any harm results from the proper use of contraceptives. Moreover, statistics based on the work of various birth control clinics, some of which have now been running for a period of nine years, go to prove that, provided reputable contraceptive measures are used, and used properly, in appropriate cases, no pathological results ensue.

On the other hand, there is undoubted evidence that unsuitable methods wrongly or carelessly applied, without previous medical examination, may cause considerable physical damage. This is surely another excellent reason why the medical profession should be willing to shoulder its responsibilities in this matter.—I am, etc.,

Crediton, Devon, May 25th. MARGARET C. N. JACKSON.

TREATMENT OF MAMMARY CANCER BY RADIATION.

SIR,—In his letter in the *Journal* of May 24th (p. 975) Dr. Douglas Webster honours me by devoting considerable space to controverting the views I have expressed as to the possible value of secondary radiation. The matter is of academic interest only, at any rate at present, and I think it would be a pity if your readers got the idea that there is any serious difference of opinion among radiologists as to the value of radiation in breast cancer. I should therefore like to emphasize the points on which I find that Dr. Webster and myself are in agreement.

I said in my letter of May 17th (p. 926) that my experience did not coincide with that of Sir Lenthal Cheatle, to the effect that only those forms of mammary carcinoma with a great tendency to metastasis are locally affected by *x* rays. I said that in the majority of cases regression occurs, and I find that in Dr. Webster's view this is so.

I am in agreement with Dr. Webster in his advocacy of pre- and post-operative radiation, which I am certain reduces the percentage of recurrences. I entirely concur with his views as regards the risk of trauma in a growth which is not being forthwith removed. As I said, it has been this fear which has kept me from injecting substances for secondary radiation into breast tumours, and I am interested to hear that Dr. Webster has seen rapid metastasis after treatment by buried radium needles. I feel sure that if radium needles are to be so used they should at least be combined with suitable external irradiation, and that the cases should be followed up, just as they are after operation.

While on this subject of trauma, I feel that I must say once more what I have been preaching for years—that specimens removed from a breast for microscopical examination should, whenever possible, be taken out by the diathermic knife. Modern improvements in apparatus make this an easy matter. If the electric knife is not used, then *x*-raying beforehand is all the more necessary as a safeguard.—I am, etc.

London, W.1, May 24th. F. HERNAMAN-JOHNSON.

ANAESTHETICS FOR SHORT OPERATIONS.

SIR,—As an onlooker, living in the Antipodes, I have been interested in the correspondence on anaesthetics for short operations. Most of the views expressed I think need qualification. Thus, chloroform is suitable as a means to open ether anaesthesia, but during its administration the patient's head and shoulders must be well raised—that is, he must be in a sitting or in a semi-recumbent position. During induction the chloroform mask should never be brought directly in contact with the patient's face. It should be held at least an inch from the face, and then very gradually be brought nearer.

The idea that the recumbent position is the correct one to adopt during induction is incorrect. Every general anaesthetic, even chloroform, causes cerebral congestion during induction, and this is exactly what the anaesthetist desires to avoid. Cerebral congestion leads to cerebral excitement and stimulation, and thus to struggling, the effect of which is to throw an extra strain on the heart. The result may be collapse and even death, not necessarily at the time of induction, but later on during the operation, owing to the strain thrown upon the heart in the early stages.

Some correspondents advocate somnoform as against open or semi-open ethyl chloride. Open ethyl chloride, properly administered, is one of the safest of all general anaesthetics. We use practically nothing else at the Eye and Ear Hospital, Melbourne, for short operations and for induction to open ether. Closed ethyl chloride is in a different category, and may bring on a stage of semi-collapse and cold sweat. In other words, ethyl chloride, like every other general inhalation anaesthetic, requires a free supply of air during induction. The oxygen cylinder is unnecessary, the surrounding air is enough. Somnoform, which is mainly ethyl chloride, with the addition of methyl chloride and ethyl bromide, when used by either the semi-open or closed method, is not so apt to produce these signs of depression. But somnoform is not so pleasant an anaesthetic as properly administered ethyl chloride. In fact, no closed method of administration is as pleasant as an open one. Somnoform is the chief anaesthetic used at the Melbourne Dental Hospital, except for children, to whom open ethyl chloride is given.

One of the most pleasant of all methods is chloroform induction to a patient sitting comfortably in an armchair. The lungs have free play, and there is no embarrassment of the heart by a loaded stomach or by an enlarged liver, or by the abdominal organs pressing up against the diaphragm. Nitrous oxide, and nitrous oxide and oxygen, have many advantages, but they are largely overrated. By means of open ether, using the absolute minimum of anaesthetic and the maximum of air, better results may be obtained for both the patient and the surgeon than by nitrous oxide and oxygen. The same remark applies to ethylene. This is a most overrated anaesthetic. It is not pleasant to take; it causes a more marked feeling of congestion in the brain than does chloroform, nitrous oxide and oxygen, somnoform, or ethyl chloride; it is more apt than nitrous oxide to bring on nausea; it is liable to cause an explosion. Endotracheal anaesthesia, too, is overrated; the argument that it prevents the admittance of blood to the lungs is incorrect. The opposite is the case if *deep* endotracheal anaesthesia is used, for there is a distinct tendency for blood to pass into the lungs by *conductivity* down the outside of the catheter, the return current not preventing this from happening. An anaesthetist should always try to retain the swallowing reflex during operations upon the mouth; the best means of doing this is not by endotracheal, but by nasopharyngeal or pharyngeal anaesthesia. A considerable number of lung complications, and laryngeal irritation and even ulceration, have followed endotracheal anaesthesia; such complications would never have occurred under properly administered nasopharyngeal or pharyngeal anaesthesia, or even under ordinary inhalation methods.—I am, etc.,

Melbourne, April 14th R. W. HORNABROOK.

VASOSTOMY IN GONORRHOEAL ARTHRITIS.

SIR,—One swallow does not make a summer, but the dramatic result obtained tempts me to put my solitary experience on record.

A man, aged 25, incurred infection on April 6th, 1929. Purulent urethral discharge was noticed on April 20th, and the patient attended a clinic for venereal diseases on the following day. The right knee-joint became painful and swollen on April 30th, soon after the development of a right orchitis. On May 4th I met him hobbling homewards with a stick. That evening he had a temperature of 101.4° F., with a copious purulent urethritis and a diffuse painful enlargement of the right knee-joint.

What was the prognosis? Four to six months at considerable expense appeared not unlikely. A communication by Mr. J. F. Peart on vasostomy recurred to my mind. Mr. Peart saw the patient on May 6th; two days later he opened the right vas and injected 10 *c.cm. of a 20 per cent.* solution of argyrol. On May 12th the left vas was opened and injected. No irrigation or other treatment was carried out after the date of the first vasostomy, but by May 22nd all discharge had completely ceased, the knee-joint was comfortable, and the swelling negligible, but there was some pain and swelling in the second toe of the left foot. Three graduated doses of detoxicated gonococcal vaccine were injected at weekly intervals. After the second injection all joint swellings completely disappeared. Prostatic massage produced some threads in the urine, but *no gonococci* were detected. After a brief holiday the patient resumed his work in the second week in June, after provocative meals and the free consumption of alcoholic beverages had failed to produce any untoward symptoms. A year later there has been no recurrence, and the urine is perfectly clear.—I am, etc.,

Edgware, Middlesex, May 22nd. GERALD MORIARTY.

SCHOOL ANTHROPOMETRY.

SIR,—The review in your issue of May 17th (p. 909) of Franzen's *Physical Measures of Growth and Nutrition* does not commend itself to all who have been associated with school hygiene in England. Instead of damning with faint praise, your reviewer should have been able to appreciate the value of biometric methods, which by much labour can sometimes extract grains of truth obtainable by no other means. This publication of the American Child Health Association is perhaps one of the clearest examples of the application of these methods to school hygiene. It exemplifies the establishing of a reliable control on the value of some of the mass of observations whose assessment hitherto has tended more to platitudinous writings than accurate analysis.—I am, etc.,

Edinburgh, May 26th. JAMES KERR.

AN OBSCURE EXANTHEM.

SIR,—I was interested in the letter headed "An obscure exanthem," by Drs. Cantor and Shulman, in your issue of May 24th (p. 976), and should like to know if any of their cases showed enlargement of the posterior occipital glands. I have recently had a case—a girl aged 12—in which the symptoms and physical signs were identical with those described, except that the pain was cervical rather than lumbar, and there was enlargement of the posterior occipital glands. Although the child is now otherwise well, and it is five weeks since the onset of the disease, the pain and glandular enlargement still persist.—I am, etc.,

Teddington, May 25th. J. O. GELDARD, M.B., B.S.

Medico-Legal.

HERBALIST SENTENCED FOR MANSLAUGHTER.

REX *v.* MASSEY.

A HERBALIST, John James Massey, was tried at Manchester Assizes on May 21st and 22nd before Mr. Justice MacKinnon on an indictment charging him with manslaughter. The prosecution alleged that in his treatment of Mrs. Annie Neal of Oldham, who was suffering from cancer of the breast, he had been criminally negligent. The prisoner was found guilty and sentenced to fifteen months' imprisonment.

Case for the Prosecution

According to the prosecution Massey had been for many years a cotton spinner before going into business at Oldham as a herbalist; he possessed no medical qualifications whatever. In September last the deceased woman felt a small lump about the size of a marble in her right breast; it appeared to be just under the skin and could be moved about. After a talk with her sister-in-law she showed the lump to the prisoner at his shop, asking if he could do anything for it. The prisoner said that he could cure it in a few days; he gave her some ointment and advised her to massage the part every day. Mrs. Neal paid him 2s. 6d., took away the ointment, and was told to call again in the following week. She did so, and went on for many weeks paying him about the same sum for each supply of ointment. In January she was getting anxious, and the

prisoner told her that the lump was a tumour which he could cure; he said he was satisfied with the progress she was making. Notwithstanding a large haemorrhage from the breast in the middle of January, the prisoner went on attending her, apparently quite unimpressed with the gravity of her condition. He continued the treatment with massage and ointment until February 27th, when Mrs. Neal, feeling ill with what she called "windy spasms," sent for Dr. Henry Mathers of Oldham, and she was seen also on the following day by Dr. Mathers's partner, Dr. Shaw, when it was obvious to both medical men that her condition was very serious indeed. They were told that someone else was treating her breast and that they need not concern themselves with it, whereupon they declined to accept responsibility for her treatment. Two days later the prisoner was informed by Mr. Neal that two doctors had seen his wife's breast and had said it was septic. Massey denied that it was septic, saying, "It is doing champion." Three days later, however, he called in another person, unregistered in this country, but known as Dr. Mellor, who said, "There is only one cure for that, and that is the knife." He advised Mrs. Neal to go to Dr. Marcus Mamourian of Ashton, who, when he saw the woman's condition, sent her home and told her to see her own doctor. She was then sent to hospital and died on March 25th, death being due to blood poisoning and cancer of the breast.

The prosecution asked the jury to say that Massey rashly and negligently undertook the treatment, that he was incompetent, and that not only did he discourage the family from sending for their own medical adviser, but his persistent massage of a cancerous growth must have had the worst possible effect.

Dr. R. P. Parker, superintendent medical officer of Oldham Municipal Hospital, said that from the moment of her arrival in hospital Mrs. Neal's was a hopeless case. The treatment described as being given by Massey was very bad; it had aggravated a disease which might have been diagnosed early and cured by proper treatment.

Drs. H. Mellor Fort, M. Mamourian, G. H. Shaw, and Frank Radcliffe gave confirmatory evidence to the effect that if Mrs. Neal's condition had been recognized and she had been operated on in September she would have had a very good chance of cure. Dr. Mamourian said that when he examined her before she was taken to hospital he found the worst cancer of the breast he had ever seen, and her condition was hopeless.

Mr. S. E. Mellin, public analyst for Oldham, said that he had analysed 11 boxes of ointment, 2 plasters, and 9 bottles of liquid handed to him by the police. They were of an everyday character and non-poisonous, with the exception of one exhibit—a small box of ointment—which on analysis was found to contain 34.4 per cent. of salicylic acid.

Summing-up and Sentence.

In the course of his charge to the jury, which occupied fifty-five minutes, Mr. Justice MacKinnon said that according to his knowledge Massey might have done his best, but that was not the standard to apply, because if a person set up to do something which required skill of a certain degree, it must be implied that he had that degree of skill and exercised it properly.

The jury, after an absence of twenty-seven minutes, found the prisoner guilty.

In passing sentence the judge said that Massey had been found guilty on overwhelming evidence; that without the slightest equipment, education, or training, he had set out to practise what was the most difficult of all sciences, and one which most concerned the health and happiness of his fellow creatures. The jury's verdict meant that beyond a doubt Massey had hastened the sufferer's death.

An application that the sentence should be served in the second division was refused.

CANCER TREATMENT: UNQUALIFIED PRACTITIONER SUED BY PATIENT.

BURRELL *v.* EVANS.

IN the King's Bench Division, before Mr. Justice Charles and a common jury, the hearing opened on May 14th, and continued for eight days, of a case in which Mrs. Amelia Burrell, aged 47, of St. John's Wood, sought to recover damages from Mr. David Rees Evans, an unqualified practitioner, of Ashburn Place, S.W., for personal injuries which, she alleged, she had suffered through his negligence.

The case of the plaintiff was that the defendant represented and thereby warranted to her that he could permanently cure her of cancer in three months, that by his treatment, which was herbal, he had permanently cured many persons suffering from cancer, and that he was qualified and competent to cure her. The representations were partly oral, and partly contained in a booklet and in a pamphlet reprinted from *Light*, and the plaintiff alleged them to have been false to the defendant's knowledge, or made recklessly, not caring whether they were true or false; further, that the defendant was negligent by wrongfully treating her when he was an unqualified practitioner by applying caustic fluid to her body, and, by his advice, preventing her from consulting a qualified practitioner.

The defendant admitted that he was medically unqualified, but said that the plaintiff was aware of this. He denied that he warranted his cure, or represented that he had permanently cured many persons suffering from cancer. He also denied all the other allegations, and said that the plaintiff had failed to undergo the entire treatment. He had acted in complete good faith, he believed the statements he had made, he was not negligent, and the plaintiff had not suffered injury from his treatment.

Case for the Plaintiff.

Mr. H. S. Simmons, for the plaintiff, said that in September, 1928, she discovered that she was suffering from cancer of the breast. She received a circular from the defendant, advertising that he was in a position to cure cancer. It was headed, "The Cardigan Cancer Treatment. . . . Administrator, D. Rees Evans," and stated:

"The Evans Cardigan Cancer Treatment was discovered by my late father and uncle (Messrs. Daniel and John Evans of Cardigan) 30 years ago. Since its discovery, and in the years 1906–13 it resulted in the invasion of Cardigan by cancer patients from all parts far and near. It was universally reported on by the press at that time, but owing to my war service, also the demise of my father in 1912, also my uncle in 1919, this treatment had become dormant until my release from the Army in 1919. Since that time I have exhausted volumes of paper (also my patience) in appealing to recognized research institutions to hold an impartial inquiry into the results of this treatment—results covering hundreds of cures effected 30 years to the present time. . . ."

There were appended "Testimonials and sworn statements from a few cured cases, 1897–1927." The plaintiff called upon the defendant, who, she said, looked at her breast, told her it was cancer, and that he could cure her in three months. The fee agreed upon was two guineas a week, but no money had been demanded or paid. His "treatment" consisted in taking a brush out of his pocket, dipping it in a fluid, and painting her breast; a lettuce leaf was then applied under a piece of gauze. The pain was intense, but the plaintiff persisted in the treatment until December, 1928, when she declared that the agony of the treatment was almost more than flesh and blood could bear, and she left off treatment, eventually seeing a qualified practitioner, and on his advice went to the Cancer Hospital, where radium was applied, with partial success. Counsel alleged that the result of the plaintiff's treatment was that she now suffered from partial paralysis. In October, while she was undergoing Mr. Evans's treatment, a request having been made by defendant to a London newspaper to publish something about the treatment, and the newspaper replying that it would do so on a favourable report from two competent medical men, two medical men called on the defendant and saw plaintiff and another lady under treatment, but they reported that the treatment was ineffectual, and no commendation appeared in the newspaper.

Mrs. Burrell, in evidence, said that the defendant when he examined her asked no questions, but spoke of himself as penalized by the medical profession, saying also that he was for four years at Liverpool University, but did not take his examination, because his qualification as a medical man would have meant that his cancer formula would have had to be surrendered to the profession, which he did not desire. She agreed, on cross-examination, that he had not been mercenary with regard to fees. He was negligent in the sense that he increased her cancer by some irritant.

Mr. Jocelyn Swan, senior surgeon at the Cancer Hospital, said that he was one of two medical men who attended at the defendant's house when Mrs. Burrell and another lady were receiving treatment. He asked to be shown the formula, but this was refused. Mr. Evans saying that it was lodged in the name of his wife and another person in case anything happened to him. His treatment was to paint a localized area with a brown fluid. Two months later Mr. Swan again saw the plaintiff, who in the meantime had undergone a change for the worse, and on his direction, and on the understanding that she gave up defendant's treatment, she was admitted to the Cancer Hospital: she was not at that time in a condition for treatment, but three months later she was again admitted, and radium was applied, with some local improvement. He added that Mr. Evans did not clean out the surface of the ulcers before painting, nor, apparently, did he sterilize the brush. In reply to Mr. Beyfus, counsel for the defendant, Mr. Swan said he thought that operation could cure cancer; radium had given good results, but the time was too short to say whether or not they were lasting. Caustic treatment, which was what the

defendant applied, was of no value in cancer of the breast. With regard to certain of Mr. Evans's cases in which the disease, it was claimed, had been completely arrested, the witness pointed out that there was no definite evidence that they were originally cancer. He agreed that he was impressed by the defendant's good faith, and that he gave him and his colleague every facility for examining the cases.

The attention of the witness was drawn to an article in the *British Medical Journal* of November 16th, 1929 (p. 911), entitled "The radium problem: statement by the Radium Commission." Mr. Swan said that the article was published as a warning against the use of radium in the hands of people who had not scientific training.

Dr. Stanley Wyard, assistant physician at the Cancer Hospital, said that he went with Mr. Swan to the defendant's house in October, 1923, and there saw the defendant treat two patients, one of whom was the plaintiff. Mr. Evans merely painted the surface of the breast with a brownish fluid, placed a lettuce leaf over the painted part, and covered it with lint. The defendant showed him photographs of patients who were said to have been cured by the Evans treatment. Some of the photographs were faded, and it was difficult to tell what the condition was, but so far as he could judge the diseases were not of a cancerous nature. He agreed with Mr. Swan that at that time the plaintiff's was an operable case, but on a second examination, in December, her general condition was distinctly worse, and she was not then operable. In cross-examination he admitted that he was a little cynical about claims for cancer treatment, receiving as he did four or five such claims every month. He was a member of the committee set up by the Ministry of Health to investigate the cause and treatment of cancer. Mr. Evans appeared before that committee, which was unanimously of opinion that no case had been made out and that no further investigation was desirable.

Professor W. S. Lazarus-Barlow, for over twenty years director of cancer research at Middlesex Hospital, said that he had examined the plaintiff and agreed with two other medical witnesses that she was now inoperable. He testified that Mr. Evans appeared before the Cancer Committee of the Ministry of Health, of which he was chairman, with documents and photographs of cases which he wished the committee to investigate. The medical officers of health in the towns where the patients lived were written to, but in the majority of cases the patients were dead or untraceable. In two or three instances where definite information was obtained it was not of such a character as to lead one to suspect that the suggested cure had taken place.

Dr. J. F. Berry of Wigan gave evidence as to the alleged cure by the defendant of a man who was said to have suffered from cancer of the tongue for two years; the man was a patient of his, and the disease from which he suffered was not cancer; it was a non-malignant tumour.

A succession of witnesses, the names of several of whom the press were asked not to mention, then gave evidence. One woman said that after a successful operation at hospital she was treated by defendant for a small spot on the chest, which, he said, in a few months would be as large as a crown. She paid £40 for his treatment. She could not say whether he cured her of anything; she still had a good deal of pain. A reference to the case was in the defendant's pamphlet, certifying that she was "enjoying splendid health," but she said that she did not write this—in fact, she could not write—nor did she dictate it, or agree to its publication. A man, a railway worker in Liverpool, said that he was treated for a lump in the cheek. Defendant told him that his fee was £12, but he abated £3 of this as he was an ex-soldier. Two letters appeared in the defendant's pamphlet purporting to be testimonials from this witness, and the witness said that the letters were prepared by the defendant himself and he signed them. Another witness, a Liverpool butcher, said that he was treated for a lump in the tonsil; he did not write the printed testimonial, but he signed it after glancing at it. The judge pointed out that the testimonial contained vital misstatements. It began boldly: "For years I have been suffering from septic throat, and two years ago eating and drinking had become nigh impossible." It also stated that he had since been examined by a medical man. Witness said that he was afterwards seen by an Italian, who was said to be a doctor, while the defendant stood outside.

Professor Lazarus-Barlow, recalled, gave evidence as to defendant's formula, which in the meantime had been handed in. He recognized the majority of the roots mentioned, many of which were old wives' remedies. His view was that the lotions would not constitute a cure for cancer.

Case for the Defendant

Mr. Beyfus, in opening the defence, said that the main issue was the charge of fraud: whether the defendant honestly believed he could effect cures, or whether he was a fraudulent quack. If the verdict of the jury could induce the medical profession to give up its prejudice against unqualified men, break down the barriers of professional etiquette, and at length obtain a real investigation of the defendant's claim, then, indeed, this would be a test case in the interests of humanity.

The defendant, giving evidence on his own behalf, said that his age was 38. His father and uncle treated patients for growths, malignant and otherwise, at Cardigan, and he had assisted them since he was 15 years of age until their deaths. Afterwards he practised alone, first in Swansea and Cardiff, then in Liverpool, and in 1927 he came to London. For the last ten years he had been trying to get his treatment investigated by the medical profession, and in 1923 he appeared before the Cancer Committee of the Ministry of Health and produced documentary evidence, but he never heard again from the committee. He was asked to send his booklet to the plaintiff, and she came to see him, but he never guaranteed a cure. Against his instructions, she removed the dressings and left the treatment incomplete.

In cross-examination, he denied that he had ever told the defendant that he had attended at Liverpool University. He described his experiences as a lad at Cardigan, where as many as 200 patients were treated in a day. His father and he treated the patients in the "surgery," and his uncle visited people in their own homes. He was in Swansea for about six months, but could not get a practice there. He did fairly well in Liverpool. With regard to his formula, this was left to him and to his sisters by his father and uncle; he had deposited the written formula in a bank. Had he felt that the Cancer Committee intended an honest investigation, he would have given up his formula, but he declined in open court to say what the formula was. His formula was his living, which was precarious. He denied that there was any irritant in the lotion. Mr. Evans was closely questioned by Mr. Simmons and by the judge on his printed testimonials. His lordship pointed out similarities and even identities in the phrasing of the different letters. He said that one patient had asked him to write out a testimonial and bring it to her for approval. Asked what was the maximum fee he charged to patients, he said that it was generally £6 a week, which was reduced to poorer patients. He put in a letter received from the Ministry of Health in 1924:

"I am desired by Mr. Wheatley [then Minister] to return the letter about the alleged cure of cancer. The correspondence has been referred to the Cancer Committee of this department for consideration. This committee consider it essential that they should be furnished with information on one or two points: (1) the composition and method of preparation of the fluid; (2) authentic records of cases in which the fluid has been successful in cure; (3) evidence that the fluid is going to do more good than the treatment usually employed and that it will do no harm."

His Lordship: A very reasonable and proper letter.

The defendant's wife said that she assisted her husband, having learned how to apply the treatment by watching him continually. She was cross-examined as to her own and her husband's bank books, and after putting certain questions to the witness, his lordship said that it seemed clear that, since this action commenced, the defendant had been unloading his banking account and putting every penny into his wife's.

Dr. J. E. Bolton said that he had been in practice for twenty-eight years, and was now practising at Yeovil. He had no special knowledge of cancer, and cases which he diagnosed as cancer he sent to specialists. He had known the defendant for two and a half years, and had seen him treat cases. In one case he was satisfied that he had effected a cure. In his view the ferments used in this treatment travelled down the side of the tumour and cut off the blood supply, with the result that the dead foreign body was eventually expelled. His opinion was that the defendant was a truthful man, although he agreed that there were inaccuracies in his pamphlet.

Mr. H. Swaffer, a journalist, said that he wrote the article in *Light* which was reprinted in the defendant's pamphlet. His desire was to get an investigation of the defendant's treatment. He made long inquiries to check his statements. He had himself made no special study of cancer. He took one doctor to see Mr. Evans's treatment; the doctor made no criticism, but said that he would like to see the case again in three years. The defendant showed him, at least thirty photographs of growths. Asked how he could tell from photographs whether the growths were malignant, Mr. Swaffer replied that they looked malignant, there were statements on the back of the photographs, and the cases could not all have been wrongly diagnosed. He agreed that in the interests of humanity it would be well if Mr. Evans would give up his formula, but what he wanted was an investigation.

About eight patients or friends of patients of Mr. Rees Evans were then examined on behalf of the defence. It was again asked that their names should not be published. One woman stated that she first consulted Mr. Evans in September, 1926; previously she had been attended by qualified medical men, who had put her on diet. She went to him as a cancer case.

She suffered from acute attacks of pain in the breast, and there was always a nagging pain. There was also a lump which increased in size. After Mr. Evans's treatment a scab formed, which eventually fell away. The treatment lasted about six months, and there was now complete healing; she had no pain, and she could do things she had never been able to do before.

Another woman, from Kingsbury, stated that she consulted her doctor for a lump in the left breast. He advised her to see a specialist, who sent her to St. Mary's Hospital, where he performed an operation on the glands and inserted two radium tubes, which were there for two days. She was afterwards sent to Mount Vernon. The effect of the radium treatment was to cause severe pain, which continued after the radium was removed, and she was again received as an in-patient at St. Mary's. Radium was again inserted, and left in for six days. Eventually she left hospital and continued treatment under her own doctor. Again, later on, she returned for treatment, and twenty-one radium needles were inserted. She was finally discharged in November, 1929. On January 8th, 1930, she began treatment under Mr. Evans. At that time she could not eat, could hardly sleep, and was shaken up in every way. The pain she suffered under Mr. Evans's treatment was incomparably less severe than that which she suffered under the radium. She was still continuing treatment under Mr. Evans. The lumps had decreased in size; the first scab that came away weighed six ounces. In her general health she was now very well, and had practically no pain. Mr. Simmons asked this witness only one question: "Would you have any objection to Mr. Swan or Professor Lazarus-Barlow examining you?" to which the witness replied, "Yes, I think I would." The judge said that there was no medical evidence as to the exact condition of this woman before she went for treatment.

Another witness stated that she had suffered from cancer of the breast and had been treated by three medical men. One breast was removed two years before she consulted Mr. Evans. She started treatment under him, on account of great swelling and pain, in May, 1928, and continued for fourteen weeks. At the end of treatment she was quite well. A lump had entirely disappeared, and she was better now than she had been for four years.

Another witness, a man, said that an ulcer on his tongue had cleared up as a result of the treatment. He agreed to be examined in court by Dr. Wyard, who afterwards reported to his lordship that there remained a scar on the tongue in the centre of which was a small warty growth, and there was another warty growth elsewhere. There was no evidence that it was a case of cancer or ever had been.

Another woman, from Cheshire, stated that she consulted a cancer specialist at the Northern Hospital, Liverpool, but afterwards placed herself under Mr. Evans. Treatment began in September, 1923, and continued for four months, at the end of which the lump came away, and her general health greatly improved; she had increased two or three stones in weight. Not being a good scholar, she got Mr. Evans to write a testimonial, but she told him what to say.

Another patient, a man from Warrington, stated that he had been treated for a stomach condition. He had undergone a short-circuiting operation, but this proved unsuccessful, and he was treated by Mr. Evans, the treatment continuing for one year and eight months. He was given medicine at the rate of one pint a week. He had been considerably better since that operation, though he still suffered from periodical vomiting. Another witness stated that his mother was treated for a growth in the cheek by defendant's father in 1907, when she was 70; the growth was removed, and she lived to be 84, dying from another cause. Another woman, from Hove, stated that she underwent two operations as a cancer patient, and as the trouble recurred she consulted Mr. Evans in 1928, and he treated her by painting the affected part with lotion, the treatment lasting nineteen weeks. She paid nine guineas a week—six guineas for treatment and three guineas for board and attendance—and she regarded it as very reasonable, considering the care and attention she received.

The Judge's Summing Up.

After counsel had made their closing speeches, which occupied almost an entire day, Mr. Justice Charles proceeded to sum up. He said that the gravity of the case could hardly be exaggerated, for the plaintiff, who was suffering from cancer of the breast, was, at the time she underwent Evans's treatment, operable, and might have been among the 80 per cent. of such cases which, according to Mr. Swan, were cured by operation. She became inoperable after three months' treatment. It appeared from the plaintiff's evidence that he did not treat her with the fluid made up from his formula, but that he applied Venice turpentine—in effect, a method of burning away with a caustic.

His lordship described the defendant's booklet, *The Cardigan Cancer Cure*, as "sodden with misstatements." It contained many testimonials written, not by the persons who said they had received benefit from the treatment, but by a man who apparently went round collecting them on behalf of Mr. Evans. In one instance Mr. Evans had admitted in the witness-box that a growth was not malignant, and yet in his booklet, in describing that case, he called it a malignant growth of stomach and bowel. It was not necessary that everything in the booklet should be untrue for the jury to find that there was fraud. If there were statements which were patent misrepresentations—in some cases inventions—to the knowledge of Mr. Evans, it was open to the jury to find that the giving of that book to induce this woman to undergo treatment was fraudulent misrepresentation.

Turning to the evidence of Mr. Swaffer, the judge said:

"How any responsible journalist can write such wicked misleading nonsense as that, when dealing with so terrible a thing as cancer, I cannot conceive. He sees photographs of 'malignant growths.' He was asked how he knew that they were malignant growths. There was no more diagnosis than from a photograph. He said that Mr. Evans showed him cancers in a bottle. I asked him myself, 'Do you know anything whatever about cancer or how to recognize it?' and his answer was, 'No; I know nothing.'"

Mr. Swaffer had gone on to make an unwarrantable, discreditable, unfounded attack on the great hospitals of this nation. He had said that little was done in hospitals except to perform operations which only delayed inevitable death.

"You heard the question I asked him, and you observed his silence. We now know that in breast cancer 80 per cent. of operations are completely and entirely successful. Mr. Swaffer would divert people from hospitals, if he could, to Mr. Rees Evans, and Mr. Rees Evans, by the republication of his paper, endeavoured to do the same. . . . Dealing with a matter so appallingly serious as cancer, I say deliberately that the writer of that article [the article in *Light*], who says he is a well-known investigator of facts, but who has investigated not a single fact, who has put a mass of hearsay into the paper, with undesirable and improper comments about hospitals, is a menace to the community of sufferers from this terrible disease."

Mr. Evans had said that he was running his cure bona fide. After reading his book, the jury might have some doubts about that. But assuming that he was practising bona fide, and his formula was beneficial and even curative, that did not excuse him for making this long series of misrepresentations in the book.

Passing to the question of negligence, his lordship said that a man who took money to treat people held himself out with a certain qualification and competence to administer the treatment. If he possessed no skill and no knowledge, then he was professing to do something which he could not do. One question was whether he ever used this formula at all in the case of Mrs. Burrell. She and two other witnesses had spoken of being painted with a thick, mahogany-coloured, viscous fluid, and that was not like the liquid in the formula. The defendant had treated Mrs. Burrell by burning, one of the oldest and most cruel methods of getting away the growth. Mrs. Burrell had said that the agony was almost indescribable, and the result was partly to paralyse her. Instead of effecting a permanent cure it left the patient much worse than when the treatment was started. If the jury believed that the treatment was negligent—so negligent, indeed, that had Mrs. Burrell died under it, he might have found himself in the criminal dock charged with manslaughter—they would find accordingly.

Discussing finally the question of damages, his lordship said that it was no part of his province to suggest a sum. No damages could compensate the plaintiff for what she had suffered, for had she stuck to her doctor and not been lured away she might have been operated on and have been saved from becoming a hopeless cancer patient. The jury must do their best in assessing damages. The figure must not be a ridiculous one, but it should be substantial, and the jury must disregard the fact that the defendant had denuded his banking account in favour of his wife.

Disagreement of the Jury.

His lordship left four questions to the jury:

1. Did the defendant make fraudulent misrepresentations to induce, and did he induce, the plaintiff to enter into a contract for treatment by him?
2. Did the defendant warrant to cure her permanently in three months, and was the warranty broken?
3. Was the defendant negligent in his treatment of the plaintiff?
4. Damages.

The jury were absent for more than two hours, and on their return they intimated that they were unable to agree upon answers to the first and third questions, and in regard to the second, they were of opinion that the defendant did not warrant to cure the plaintiff in three months.

Mr. Justice Charles said that this amounted to a disagreement, which was an unfortunate result of the trial. He discharged the jury, and exempted them from further service for seven years.

Judgment for Defendant Ordered.

Following the answers of the jury, an application was made on May 27th on behalf of the defendant, Mr. Evans, that judgement be entered for him in the action on the ground that he had succeeded on the issue of the warranty.

Mr. Justice Charles said that although the matters in dispute were separated in the questions put to the jury, the action was a whole. He therefore refused the application, and ordered Mr. Evans to pay the costs of it.

Universities and Colleges.

UNIVERSITY OF OXFORD.

SIR ARTHUR KEITH will be among the recipients of the honorary degree of Doctor of Science, to be conferred in the Sheldonian Theatre on June 25th.

UNIVERSITY OF LONDON.

THE Dunn Exhibitions in Anatomy and Physiology for 1930 have been awarded to A. Birnbaum, an internal student of the London Hospital Medical College.

UNIVERSITY OF MANCHESTER.

THE jubilee of the Manchester University and the eightieth anniversary of its foundation as Owens College was celebrated last week.

After a commemoration service in Manchester Cathedral, at which the Archbishop of York preached the sermon, a congregation of the University was held in the Free Trade Hall on May 23rd, when the Chancellor, Lord Crawford of Balcarres, delivered an address.

A number of honorary degrees were conferred, including that of LL.D. bestowed upon the American Ambassador, General Dawes; the Earl of Derby; Mr. Philip Snowden, Chancellor of the Exchequer; Miss Sara Margery Fry, Principal of Somerville College, Oxford; and Mr. A. H. Worthington, chairman of the council of the University. The honorary degree of D.Sc. was conferred upon Professor J. Lorrain Smith, F.R.S., who retired from the Chair of Pathology in Manchester University in 1912, on his appointment as Professor of Pathology in the University of Edinburgh.

UNIVERSITY OF WALES.

THE University of Wales announces in our advertisement pages that the following scholarships will be awarded in the session 1930-31, provided suitable candidates are forthcoming: Cecil Plosser Research Scholarship (value £250), for research in the department of tuberculosis; the Mrs. John Nixon Scholarship (value £150), for research in the department of medicine and medical pathology; the Lord Merthyr Scholarship (value £200), for research in the department of surgery; and the Ewen Maclean Research Scholarship (value £150), for research in the department of obstetrics and gynaecology. Particulars of the award of the scholarships and forms of application may be obtained from the Registrar, University Registry, Cathays Park, Cardiff.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—E. C. Dymond, R. F. T. Finn, E. A. Freywirth, H. G. Hind, J. H. Johnston, E. Lethem, A. Liberis, J. Ross.
MEDICINE.—G. P. Charles, A. R. Edwards, J. D. B. Games, J. Ross, E. M. M. Shaw, W. H. Willis.
FORENSIC MEDICINE.—A. Buch, G. T. W. Cashell, T. C. Keble, E. H. W. Lyle, C. G. Nicol, J. Ross, C. M. Smith, A. L. Thomas, W. H. Willis.
MIDWIFERY.—G. T. W. Cashell, Y. Haig, J. Ross, A. L. Thomas, W. H. Willis.

The diploma of the Society has been granted to Messrs. A. R. Edwards, J. H. Johnston, A. Liberis, and J. Ross.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

AT the annual general meeting of the British College of Obstetricians and Gynaecologists, held in London on May 20th, with the president (Professor W. Blair Bell) in the chair, the result of the election of the council was announced.

At the first meeting of the new council, held in the afternoon of the same day, the officers were elected and the casual vacancies created by these elections were filled. Dame Louise McIlroy (London) was co-opted for the special purpose of representing women Fellows and Members.

The officers and the full council are now as follows:

President: W. Blair Bell.
Vice-Presidents: John S. Fairbairn, John M. Munro Kerr.
Honorary Treasurer: Eardley L. Holland.
Honorary Secretary: Wm. Fletcher Shaw.

Council.

London.—H. Russell Andrews, T. Watts Eden, J. S. Fairbairn, Dame Louise McIlroy (Fellows); [illegible]
England and Wales (exclusive of London).—[illegible] Sir Ewen J. Maclean, H. Leith Murray, Miles [illegible] Whitehouse (Fellows), E. Farquhar Murray, J. Eric Stacey (Members).
Scotland.—R. W. Johnstone, J. M. Munro Kerr (Fellows); E. A. Lennie, W. P. T. Hamilton (Members).
Ireland.—C. H. Lowry, Bethel Solomons (Fellows); T. M. Healy (Member).

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has commenced the committee stage of the Finance Bill this week, and has also discussed unemployment and Indian affairs. The Education Bill, which proposes to raise the school-leaving age to 15, was down for second reading, on May 29th, in the Commons, and the Coal Mines Bill for third reading in the Lords on the previous day.

The Parliamentary Medical Committee has arranged to visit the Red Cross rheumatic clinic at Regent's Park on June 2nd, and to hear an address from Sir Walter Fletcher on June 3rd about medical research.

On behalf of the Public Health Advisory Committee of the Labour party, Dr. Ethel Bentham and Mr. Somerville Hastings saw Mr. Greenwood on May 21st in order to make representations in favour of the regulation of the sale and advertisement of patent medicines. The deputation gave instances of the evils resulting from the unregulated sale of secret remedies, such as the effect in preventing persons from seeking proper treatment, the waste of money, and the danger to health, particularly from prolonged use of these remedies. The Minister was very sympathetic in his reply. He could not promise legislation during the present session, but there is understood to be a possibility that a private member's bill may be introduced dealing with only one aspect of the question in order to focus public opinion. If introduced this bill will be prepared in concert with the British Medical Association.

Milk for School Children in Scotland.

The Education (Scotland) Bill came up for third reading in the House of Commons on May 23rd. Dr. ELLIOT, who had introduced the bill, remarked that it had been read a second time without debate. Scotland, he said, had previously attached much importance to the training of the mind and not enough to the training of the body. The bill proposed to enable education authorities in Scotland to incur expenditure in supplying milk to the children attending the schools within their areas. The annual report of the Scottish Department of Health showed that only one-third of the school population received systematic medical inspection in the school year, and that seven and a half minutes was spent on each child. That cursory investigation showed that 2.4 per cent. of the children examined were suffering from anaemia and 2.5 per cent. from tuberculosis in one form or another. These figures had induced him to introduce the bill. Of these children, 22 per cent. suffered from unhealthy glands. Dr. Elliot pointed out that the bill had been amended in committee to provide that the milk supplied should be certified milk, or, failing that, the best grade available in the area. Bovine tuberculosis was understood to cause the death of 3,000 children yearly in this country. Its prevalence in the herds caused reluctance of doctors to prescribe milk and of the public to consume what was the finest food for the young of the human race. The difficulty of the provision was that only 101 herds in Scotland were licensed for the sale of tubercle-free milk, although Scotland had more than 450,000 milch cows. The bill did not differentiate between necessitous and other children, because experiments had shown that the average child in Scotland suffered from a lack of certain vital constituents. Without milk the child could not take full advantage of the foods with which it was supplied at home.

Mr. JOHNSTON (Under-Secretary of State for Scotland) said the object of the bill was desired by all the large education authorities in Scotland. Glasgow had intimated that its scheme was ready. The bill was an optional one. He pointed out that in schools where a milk ration was given the absences fell almost to nothing.

Mr. W. R. SMITH moved the rejection of the bill. He said that at present an education authority could supply what was lacking to a child which, through physical ill health or otherwise, was unable to benefit by the education which was given. The tests at present being made were with Grade A (tuberculin-tested) milk, which in some cases was pasteurized in addition. Mr. JOHNSTON intervened to say that tests in Lanarkshire were conducted with pasteurized and tuberculin-tested milk, half supplies of each. Mr. SMITH remarked that in many districts of Scotland it would be impossible to get a large enough supply even of pasteurized milk. To allow education authorities to supply children with milk which might contain tuberculosis germs would put into the hospitals thousands of cases of tuberculosis. When the bill was in committee Mr. Johnston had declared that every year 2,000 or 3,000 surgical tuberculous cases entered Scottish hospitals, and these cases were directly traceable to the poisoned milk supply. Officials of the Department of Health said the bill could not be worked by many authorities if certified or pasteurized milk had to be supplied.

Mr. BOOTHBY pointed out that schemes for the supply of milk had to be approved both by the Department of Education and

the Department of Health for Scotland. He held that the low consumption of milk in Glasgow, Edinburgh, and Dundee was responsible for the high tuberculosis rates in those cities.

Mr. MACQUISTEN thought the large local authorities would insist on the milk being certified. He wished that the bill provided for the supply of oatmeal as well as of milk—not cooked porridge, but brose, or raw oatmeal, which was the natural accompaniment of milk.

The motion for rejection was then negatived and the bill read a third time.

Mr. BUXTON, replying to Mr. Hastings on May 26th, said the total number of animals on premises on which cases of tuberculosis were reported, under the Tuberculosis Order, 1925, during 1929 was 621,396. Of these, 241,252 animals were examined by veterinary inspectors, and 15,732 animals were condemned and slaughtered, representing 2.8 per cent. of the total number of animals on the premises, or 6.5 per cent. of the total number examined. The remainder were not necessarily entirely free from tuberculosis, but presented no symptoms to bring them within the scope of the Tuberculosis Order on compulsory slaughter.

Indian Medical Degrees.

Mr. WEDGWOOD BENN, Secretary of State for India, speaking in the debate on the India Office vote in committee of supply of the House of Commons on May 26th, referred to Indian medical degrees. He said that the General Medical Council, after considerable discussion—the point had been raised many times in recent years—decided that unless an officer, called the Commissioner of Medical Qualifications and Standards, was appointed—Colonel Needham had been designated for the post—to appraise, so to speak, the standard of the medical education given in the various Indian medical colleges, the Council would be unable to continue to recognize Indian medical degrees. Owing to circumstances which he need not describe, that appointment was never completed, and the General Medical Council felt compelled to withdraw its recognition of Indian medical degrees. That was a most unfortunate thing, both for Indians and for the British. The problem was urgent, and was being urgently studied by the Government in the hope that by the creation of some all-Indian medical organization an authority might be formed which, manned and staffed in India, might be able to give those guarantees which the General Medical Council considered requisite. That something should be arranged at the earliest possible moment was in the interests of both India and this country alike.

National Health Insurance.

Mr. GREENWOOD stated, on May 22nd, in reply to Mr. Rhys Davies, that a proposal was under consideration to have a separate scheme to cover insured persons falling out of the national health and pensions insurance scheme by reason of continuous unemployment.

Sir Kingsley Wood was informed by Mr. GREENWOOD, on May 22nd, that he had not yet received a deputation from the central board of the Co-operative Union, complaining of the prohibition of payment of co-operative dividends on national health insurance prescriptions, but he hoped to receive one shortly.

Anthrax.—In reply to Mr. Dukes, on May 22nd, Mr. SHORT said that the six fatal cases of anthrax in the Liverpool, Runcorn, and Warrington districts were all reported to the Factory Department and carefully examined. The seriousness of some cases might have been aggravated by delay in recognizing the disease, but treatment was given without delay in every case as soon as it was recognized to be anthrax. To secure recognition of anthrax without delay, the Factory Department had issued for exhibition at work-places a large placard indicating symptoms, the precautions to be taken, and the urgency of medical examination in suspected cases. A small card on the same lines was being prepared for the workman to keep by him and to show to any doctor or hospital authorities to indicate that his employment involved risk of anthrax. Further special steps had been taken in the tanning industry, in which five of the above cases occurred. The senior medical inspector recently addressed a circular to hospitals in tannery districts drawing attention to risks among persons handling hides and the importance of being on the look out for possible cases among patients. In a Home Office circular to tannery occupiers the importance of prompt diagnosis and treatment was specially mentioned, and they were urged to review their arrangements for securing this and getting into touch with local hospitals. Mr. Greenwood did not think the appointment of a committee of inquiry would be likely to carry matters further, but the subject would continue to receive close attention, and he would be glad to hear of any particular suggestions.

Anthracosis.—Mr. SHORT told Dr. J. H. Williams, on May 22nd, that he had not published reports of cases of anthracosis. A list of persons alleged to have suffered from the disease was not available at the Home Office. Investigation of the effects of coal dust on the lungs had been referred to the Expert Committee on the Industrial Pulmonary Diseases, set up by the Medical Research Council. It had yet to be established that anthracosis was the cause of disablement. Meanwhile it was impossible to bring it within the Workmen's Compensation Act. He was advised that there was some evidence of special changes in the lungs due to conditions in the anthracite coalfield, but further investigation was necessary.

Vaccination and Small-pox.—Mr. GREENWOOD informed Mr. Groves, on the same day, that, from 1919 to 1928 inclusive, the counties in England and Wales with the lowest and highest percentage of primary vaccinations to births were Leicestershire and Anglesey respectively. The total number of cases of small-pox notified during the same ten years per 1,000 of the average population was 0.63 in Leicestershire (including the county borough of Leicester) and 0.02 in Anglesey.

Public Vaccinators' Fees.—Mr. GREENWOOD told Mr. Groves, on May 26th, that on March 31st last, the latest date for which complete particulars were available, 28 public vaccinators had contracts which provided for payment by salary, and 4,293 had contracts which provided for payment by fees.

The New Board of Control.—Mr. GREENWOOD stated, in reply to Mr. Winterton on May 22nd, that of the five Senior Commissioners who were to compose the Board of Control under the terms of the Mental Treatment Bill one would be a woman. It would be necessary for the two medical Senior Commissioners to possess primarily qualifications for advising upon the treatment of mental disorders. He could not promise that one of the medical Commissioners would be a woman.

Bracebridge Mental Hospital.—Mr. GREENWOOD told Colonel Heneage, on May 22nd, that the proposals for the alterations and improvements to the Bracebridge Mental Hospital required the consideration of the Ministry of Health and of the Electricity Commissioners. He would try to ensure an early decision.

Slaughterhouses in England and Wales.—In a reply to Mr. Freeman, on May 22nd, Mr. GREENWOOD said there were in England and Wales 250 slaughterhouses owned by local authorities and 16,000 private slaughterhouses. The number of local authorities who had in force, on May 13th, 1930, a by-law based on Clause 9 (*b*) of the Model Series was 358.

Mental Hygiene Congress.—Mr. GREENWOOD, on May 26th, told Mr. Mander that the British Government was represented at the recent International Congress on Mental Hygiene at Washington by Sir Hubert Bond, a medical Commissioner of the Board of Control. Sir Hubert Bond had not returned to this country, and no report had been received.

Sterilization of the Unfit.—On May 26th Mr. GREENWOOD informed Mr. Mander that he had received a communication from the Wolverhampton Town Council on the question of the sterilization of the unfit. He considered that a full inquiry must necessarily precede any action, but he could not undertake to initiate such an inquiry at the present moment.

Notes in Brief.

The increase of the population of England and Wales between mid-1927 and mid-1929 is estimated at 317,000.

Mr. Greenwood said, in reply to Major Salmon, that he had received complaints of inconvenience suffered by residents in Hanwell from odours emanating from the sewage disposal works in the vicinity. The town council had applied for sanction to a loan for the improvement of the works, and an inquiry had been held by his inspector, on whose report appropriate steps would be considered.

Mr. Greenwood informed Mr. Harris, on May 22nd, that he knew of no cases where damage to eyesight had been caused by electric signs employing the infra-red ray.

Mr. Adamson has appointed Sir William Whyte, clerk to the late Middle Ward District Committee of Lanarkshire, to be chairman of the Scottish Advisory Committee on Rivers Pollution Prevention, in room of the late Sir John Findlay.

The Services.

DEATHS IN THE SERVICES.

Colonel Maurice Knox, R.A.M.C. (ret.), died at Littlehampton on April 20th, aged 84. He was born on January 24th, 1846, was educated in Dublin, in the medical school of the R.C.S.I., and took the L.R.C.S.I. and L.K.Q.C.P. in 1869. Entering the army as assistant surgeon on March 31st, 1868, he reached the rank of brigade surgeon lieutenant-colonel on May 2nd, 1894, and retired on June 2nd, 1897. He was re-employed at Aldershot during the South African war, and was granted the rank of colonel for his services, on October 18th, 1902. He served in the Afghan war of 1878-79, was mentioned in dispatches, and received the medal. During the old regimental days he served in the 70th Foot, now the 2nd East Surrey Regiment.

Colonel Claude Kyd Morgan, C.B., C.M.G., late R.A.M.C., died on February 17th, aged 58. He was born at Inverkeilor, Montrose, on December 2nd, 1871, and was educated at Aberdeen, where he graduated as M.B. and C.M. in 1893. Entering the R.A.M.C. as surgeon lieutenant on July 28th,

1834, he became lieutenant-colonel in the long war promotion list of March 1st, 1915, and colonel on December 26th, 1917, retiring on September 22nd, 1920. While a captain, he served on plague duty in Poona city in 1899–1900, and received the thanks of the Government for his services. He served as an A.D.M.S. during the war of 1914–18, was mentioned in dispatches in the *London Gazette* of February 17th, 1915, June 22nd, 1915, January 1st, 1916, and May 29th, 1917, and received the C.M.G. in 1916, and the C.B. on June 3rd, 1919.

Lieut.-Colonel Henry Grier, R.A.M.C. (ret.), died at Guildford on April 29th, aged 75. He was born on August 29th, 1854, was educated at Queen's College, Cork, and the Carmichael School, Dublin, and took the L.R.F.P.S.Glas. in 1875, and subsequently the M.K.Q.C.P. in 1882. Entering the army as surgeon on February 3rd, 1878, he became lieutenant-colonel after twenty years' service, went on half-pay on November 20th, 1903, and retired on February 20th, 1908. He served in the South African war in 1899–1901, in charge of a general hospital with the local rank of colonel, was mentioned in dispatches in the *London Gazette* of April 18th, 1901, and received the Queen's medal with two clasps. He received the Albert medal, second class, in 1881, for heroic zeal and humanity in risking his life in an operation upon an officer (*London Gazette*, January 14th, 1881).

Obituary.

FRANK RICHARDSON BLAXALL, M.D., D.P.H.,

Bacteriologist, Government Lymph Establishment.

MEDICAL officers of health and others engaged in small-pox control will learn with regret of the death, in his 64th year after a brief illness from pneumococcal septicaemia, on May 24th, of Dr. F. R. Blaxall, a medical officer of the Ministry of Health and for twenty-three years the director of the Government Lymph Establishment.

Frank Richardson Blaxall was born on November 8th, 1866, and from University College School went to study medicine at University College Hospital. He obtained the M.R.C.S. and L.R.C.P. diplomas in 1888, and graduated M.B. of the University of London in the same year with honours in medicine, proceeding M.D. in 1890, and obtaining the Cambridge D.P.H. in 1893. After holding a number of house appointments and acting as assistant superintendent of St. Pancras Infirmary he became lecturer in bacteriology at Westminster Hospital Medical School, where he was associated with Dr. Macfadyen in important researches on "thermophilic bacteria" and on the bacteria of rheumatoid arthritis. It was not until 1896, however, that Blaxall began his life-work on anti-small-pox vaccine. In that year he collaborated with Dr. Monckton Copeman, then on the staff of the Local Government Board, in a research into the influence of "Glycerin on the Vitality of Micro-Organisms, especially of Variolous and Vaccinious Material." Before this time glycerin had been used abroad as a diluent of vaccine pulp, but its bactericidal properties had not been investigated. The results of these investigations are found expressed in the Vaccination Act of 1898, which prescribed the use of glycerinated calf lymph for public vaccination. This marked a great advance, and made way for the abolition of arm-to-arm vaccination, previously practised. Blaxall shortly afterwards joined the staff of the Local Government Board on appointment as bacteriologist to the National Vaccine Establishment, Lamb's Conduit Street, the precursor of the Government Lymph Establishment at Hendon, and for thirty-two years he was responsible for the preparation and issue of Government lymph.

Blaxall was ever improving his technique, and from the laboratory there proceeded year by year a series of papers and reports by him and his fellow workers, on the scientific aspect of lymph production; these papers included reports on research work in connexion with glycerinated calf lymph, equino variola, the cold storage of lymph, the use of oil of cloves in the preparation of lymph, and other reports to the Local Government Board and the Ministry of Health. Blaxall combined great skill and knowledge with a high sense of duty and a pleasant spirit of comradeship; in constant touch with workers in the same field abroad he was repeatedly consulted by distinguished medical men visiting this country. Indeed, his laboratory became a place of pilgrimage for colonial and foreign medical officers interested in vaccine production; he was responsible, at the request of various Governments, for the training of many of these officers, and the great majority of the directors of vaccination institutes in the British possessions are men who learned their work at Hendon under him. He served as a member of the Small-pox and Vaccination Commission appointed by the Health Committee of the League of Nations, and was a member of the Departmental Committee on Vaccination, where his long experience and highly specialized knowledge were greatly valued.

Dr. A. E. COPE, honorary secretary and treasurer of the Association of Public Vaccinators, sends the following tribute:

Every public vaccinator in England and Wales will feel the death of Dr. F. R. Blaxall as a personal loss. Although few of us, it may be, met him face to face, we always felt the impress of his personality in the promptitude with which our requisitions for lymph were met, the certainty and confidence with which we used what he supplied to us, and the courtesy and consideration which were manifest in all his communications with us. It is a boast of the Government Lymph Establishment that from the very commencement every day's demands for lymph have been issued on that day, and many a public vaccinator has recollections of times when an urgent request for lymph by telegram or telephone has brought the needed supply by first post, even at times by special messenger. The control of an establishment which, for example in the last year for which figures are published, issued nearly three-quarters of a million separate tubes of lymph, from nearly 500 calves, with a case success of close upon 98 per cent., demanded scientific and technical attainments of the highest order and administrative ability of no mean character; and when we think that this high standard of achievement had been maintained uninterruptedly for over thirty years, even through times of special epidemic stress, and through the dislocations consequent upon the great war, we can form some idea of the calibre of the man who made this task his life's work.

Self-effacing, he shrank from publicity, and was ever ready to pay his tribute to the loyalty and devotion of colleagues and staff. During the last few years we had met more frequently on the Vaccination Committee of the Ministry of Health, where his counsel was invaluable, and his criticism shrewd and informed. He was ever ready to help those of us who were engaged as teachers of vaccination, and my last visit to him was to ask him about some photographs of the establishment and its work, which had been prepared for the Wembley Exhibition and copies of which I was anxious to have for demonstration purposes. We talked about the possibility of his writing some little manual of animal vaccination embodying the results of his own experience and research. Unfortunately he has not been spared to give us what he, perhaps better than any other, could have done.

Dr. Blaxall's own contributions to medical literature, apart from official reports, have been few. One would be glad to think that he had left papers which might be collected and published as a permanent memorial of his association with the Government Lymph Establishment. Perhaps Dr. S. Monckton Copeman, through whom he was introduced to his special work, or his colleague Dr. Fremlin, associated with him for over thirty years, may be able to help in that direction. Meanwhile it is for us to pay our tribute of respect and admiration to the memory of one who was a faithful servant of the State, a fine-spirited professional colleague, and a loyal friend.

ALEXANDER HARPER, M.D.,

Consulting Surgeon to the Princess Alice Memorial Hospital, Eastbourne.

DR. ALEXANDER HARPER of Eastbourne died at his residence in Arlington Road on May 9th. He had practised in Eastbourne upwards of forty years, and was held in high regard by his professional brethren, and was much esteemed by his patients and the residents generally.

Born at Windsor sixty-nine years ago, Alexander Harper was the son of James Peddie Harper, M.D., of Windsor and London. He was educated at the University of

Durham and at St. Bartholomew's Hospital. He obtained the M.R.C.S.Eng. diploma in 1884, graduated M.B. of the University of Durham in 1884, and proceeded M.D. in 1887. He was formerly house-surgeon at the West London Hospital, resident medical officer, North-West London Hospital, and house-physician at the Victoria Hospital for Children, Chelsea. Before retiring from practice, about eighteen months ago, owing to failing health, Dr. Harper had had an active and useful career. He will be especially remembered for his valued services in connexion with the Eastbourne Provident Medical Association, of which he was the founder, and was chairman up to the time of his death. The association proved so successful in the town that it was copied in many other towns and also abroad. For many years he served on the honorary medical staff of the Princess Alice Memorial Hospital, and later was one of the consulting surgeons. During the war he rendered much-appreciated work in connexion with the Urmston Red Cross Hospital, and he also undertook many of the duties of medical men who went to the war; and for the medical services which he rendered to the many Belgian refugees resident in Eastbourne he was awarded the Medaille du Roi Albert.

Dr. Harper took great interest in the work of the British Medical Association. After serving for some years as a member of the Executive Committee of the Eastbourne Division he was elected chairman of the Division in 1914. He leaves a widow and two daughters.

Dr. ROBERT ROBERTSON, a well-known practitioner in Edinburgh, died at his residence in that city on May 18th. After graduating M.B., C.M. at Edinburgh in 1888, he obtained the B.Sc. degree in public health in the following year, being one of the first who availed themselves of this newly instituted qualification; he was a fellow student of the late Professor Ritchie, who subsequently became the first professor of bacteriology in the University. His association with Professor Ritchie was largely responsible for the special interest which he took in vaccine treatment during the later years of his life. After graduation, Dr. Robertson began general practice in the Stockbridge district of Edinburgh, residing in Royal Circus. During a considerable part of the next thirty-four years he was a member of the Edinburgh Town Council, and on the Public Health Committee his valuable service and advice moulded to a considerable extent the developments of health services in the city. Towards the year 1920 he became greatly interested in the possibilities of the use of vaccines in treatment, and he contributed numerous articles to medical periodicals dealing with this subject. An account of the treatment of neurasthenia by vaccine was published in the *Edinburgh Medical Journal*, and a description of vaccine therapy in gynaecology and obstetrics appeared in the *Transactions of the Edinburgh Obstetrical Society*; he contributed also to the *Practitioner* some two years later an article on the method of using tuberculin. About this time the strenuous work of his large practice began to prove too much for an ailment of the heart from which he suffered, and he was obliged to restrict his energies. During the eight years before his death he had devoted himself largely to vaccine treatment, after removing his practice to Melville Street. Dr. Robertson is survived by a widow, one daughter, and two sons, of whom one is a medical practitioner in Kenya Colony; he is also survived by his mother, who is still alive at the age of 104.

Dr. LOUIS FOURNIER, physician to the Cochin Hospital, Paris, who was chiefly responsible for the introduction of the bismuth treatment of syphilis about ten years ago, has died, aged 62. Other reported deaths of medical practitioners abroad include Dr. BETTENCOURT of the Pasteur Institute of Lisbon; Dr. GIORGIO RATTONE, professor of general pathology at Parma; and Dr. KARL URBAN, director of the Vienna branch of the medical publishing firm of Urban and Schwarzenberg, who was created doctor *honoris causa* by the Vienna medical faculty some years ago.

Medical News.

SIR ROBERT ARMSTRONG-JONES will deliver the fifth Macalister Lecture before the London Clinical Society at the London Temperance Hospital on Tuesday, June 24th, at 9 p.m. The subject of this year's lecture is "The evolution of the human mind." All medical practitioners are cordially invited to be present, and may bring friends (ladies or gentlemen).

LORD LAMINGTON, President of the Research Defence Society, will preside at the annual meeting of the society to be held at 11, Chandos Street, W.1, on Tuesday, June 3rd, at 3.15 p.m. The fourth Stephen Paget Memorial Lecture, on "Diet and dental disease: what we have learned from animal experiments," will be given by Mrs. Mellanby.

THE annual meeting of the governors of Epsom College will be held at the office, 49, Bedford Square, W.C.1, on Friday, June 27th, at 4 p.m., when the result of the voting for pensioners and foundation scholars will be announced.

THE Mental After-Care Association will hold its jubilee meeting on Monday, June 2nd, at Drapers' Hall, Throgmorton Street, E.C., under the presidency of H.R.H. Prince George. The other speakers will include Lord Wakefield and Sir Maurice Craig.

A MEETING of the Society for the Study of Inebriety will be held at 11, Chandos Street, W.1, on Tuesday, July 8th, at 4 p.m. Dr. E. F. Willis, medical superintendent of Rendlesham Hall, Suffolk, will open a discussion on delirium tremens, its causation, prevention, and treatment.

THERE will be a discussion on asthma at a special meeting of the Medical Advisory Committee of the Asthma Research Council on Thursday, June 5th, at 3.30 p.m., at 37, Russell Square, W.C.1. Those desiring to take part are requested to give notice to the Council.

THE Department of Research in Animal Genetics, University of Edinburgh, will be opened on Monday, June 30th, at noon, by Sir Edward Sharpey Schafer.

THE St. Cyres Lecture for 1930 on the fibroses of the heart will be delivered by Dr. John Cowan at the National Hospital for Diseases of the Heart, Westmoreland Street, W.1, on Wednesday, June 4th, at 5 p.m. Members of the medical profession are invited to attend.

THE Fellowship of Medicine announces that special lectures in preparation for the M.R.C.P. examination will be given on Monday, June 2nd, at the Royal Westminster Ophthalmic Hospital, Broad Street, by Mr. C. L. Gimlett, at 4.30 p.m., on general medical ophthalmology; on Tuesday, June 3rd, at the Medical Society's lecture room, 11, Chandos Street, Cavendish Square, at 8.30 p.m., by Sir William Willcox, on some points in connexion with the toxic effects of lead, arsenic, morphine, and cocaine, etc.; and on Friday, June 6th, in the same lecture room, at 8.30 p.m., by Dr. H. E. Archer, on the fractional test meal as an aid to diagnosis. A free demonstration will be given by Dr. S. E. Dore on Monday, June 2nd, at 6 p.m., at St. John's Hospital, Leicester Square. The subjects of special courses in June are: gynaecology, at the Chelsea Hospital for Women from June 16th to 28th (some mornings and some afternoons); dermatology, at the Blackfriars Skin Hospital from June 16th to 28th (every afternoon); medicine and surgery at the Prince of Wales's Hospital, Tottenham, from June 16th to 28th; and proctology at St. Mark's Hospital, June 30th to July 5th, these last two being all-day courses. Fees are payable to the secretary of the Fellowship, 1, Wimpole Street, W.1, from whom all syllabuses and tickets of admission are obtainable.

THE Bakerian Lecture of the Royal Society was delivered on May 29th by Professor Robert Robinson, F.R.S., who took for his subject the molecular structure of strychnine and brucine. He suggested a formula which could be used to interpret in a satisfactory manner all the chemical aspects of strychnine.

MESSRS. J. AND A. CHURCHILL announce for early publication new books entitled *Tropical Medicine*, by Sir Leonard Rogers and Major-General J. W. D. Megaw; *The Hair: its Care, Diseases, and Treatment*, by Dr. W. J. O'Donovan; and *Surgical Emergencies in General Practice*, by Messrs. W. H. C. Romanis and P. H. Mitchiner.

WE have received the first issue of *Revista Espanola de Tuberculosis*, a journal published bi-monthly at Madrid under the editorship of Dr. J. Valdés Lambea, and containing original articles, abstracts from current literature, and reviews dealing with tuberculosis.

THE second International Congress for Experimental Cell Research will be held at Amsterdam from August 4th to 9th. Further information can be obtained from Professor Rhods Erdmann, Nassauische Strasse 17, Berlin-Wilmersdorf.

THE Royal College of Physicians of London will be closed on Saturday, June 7th, and Monday, June 9th.

SIR JAMES DUNDAS GRANT has been elected an honorary member of the Inter-State Post-Graduate Medical Association of North America.

THE branches of the Society of Medical Officers of Health have unanimously nominated Professor Harold Kerr, medical officer of health for the city of Newcastle-upon-Tyne, for election as president of the society for the session 1930–31. Dr. Kerr will take office in October.

THE freedom of the city of Chester has been conferred upon Dr. George Harrison. The same honour had been bestowed upon his great-grandfather and grandfather as well as upon two of his uncles.

AN Order, to come into force on July 1st, 1930, has been issued by the Home Secretary for securing the welfare of employees in factories and workshops engaged in the liming and tanning of raw hides and skins and in processes incidental to these operations. Occupiers are required to provide and keep in good condition protective clothing of suitable design and material as described in the schedule attached to the Order. Such clothing must ensure that a worker in any particular process is effectively protected from wet and damp. Adequate arrangements must be made for drying clothes, and separate accommodation provided for protective clothing as well as for garments put off during working hours. Toilet facilities must include a sufficient supply of clean towels, soap, and warm water. In the absence of other suitable arrangements a heated messroom, separated from other accommodation, must be provided for the use of employees remaining on the premises during the meal intervals; and means must be available for warming food and for boiling water. In regard to first-aid treatment, the occupier must observe the requirements laid down for factories in Section 29 (1) of the Workmen's Compensation Act, 1923; and he must arrange for a bi-weekly inspection of the fingers of workers who use solutions containing chromates or salts of chromium with free acid. He must also see that the official cautionary notices referring to the effects of chrome on the skin and to anthrax are kept posted up in the works. First-aid boxes must be equipped with a supply of impermeable waterproof plaster.

THE tenth Congress of the German Pharmacological Society will be held at Königsberg from September 4th to the 7th, when the following subjects will be discussed: problems of inflammation, introduced by Starkenstein of Prague; pharmacological problems of febrile diseases, introduced by Freund of Münster; allergy, introduced by Storm van Leeuwen of Leyden; and problems of the reticulo-endothelial system, introduced by Schulemann of Elberfeld. Further information can be obtained from Professor W. Lipschitz, Pharmakologisches Institut, Weigertstrasse 3, Frankfurt-am-Main.

THE ninety-first Congress of the Society of German Natural Philosophers and Physicians will be held at Königsberg from September 7th to the 11th, when all departments of medicine will be represented. Further information can be obtained from the general secretary, Dr. Wiegand, Ostmessehaus, Hansaring, Königsberg.

THE twenty-third Voyage d'Études Médicales will take place in the first fortnight of September under the direction of Professors Maurice Villaret of Paris, Santenoise of Nancy, and Paul Blum of Strasbourg. Visits will be paid to health resorts in Alsace, the Jura, and the Vosges.

DURING the present Exhibition of International Hygiene at Dresden, one day, June 1st, will be devoted to social hygiene, and addresses will be delivered by well-known authorities on child welfare, the care of cripples, tuberculosis, syphilis, and alcoholism.

IN order to stimulate interest in the fund being raised to provide Birmingham with a new hospital centre a business citizen has offered a gift of £100,000 provided that the list of subscriptions to be published on June 6th totals £350,000. It is estimated that the cost of the scheme in the next five years will be £1,250,000.

A FOLDER giving particulars of yachting cruises by the s.y. *Killarney* to the Scottish firths and fjords has been issued by Coast Lines Ltd., and may be obtained from all recognized tourist agencies.

DR. ERNST GRASSER, professor of surgery at Erlangen, has been made an honorary member of the German Urological Society of Berlin, and Professor Victor Klingmüller of Kiel an honorary member of the Cuban Dermatological Society.

DR. J. F. E. BRIDGER is relinquishing the post of director of medical and sanitary services of Ceylon on his retirement from the Colonial Medical Service on July 5th next.

DR. RUDOLF HÖBER, the physiologist, has been appointed rector of the Christian Albrechts University at Kiel.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9351, 9352, 9353, and 9354* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62571 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

EFFECTS OF PROLONGED ADMINISTRATION OF LIQUID PARAFFIN.

"M. H." writes: A woman, aged 53, has been taking paraffinum liq. (1 oz. at bedtime) for three years for chronic constipation. Before commencing this her weight had been stationary for years, but she has since gained 1 to 1½ lb. each month. Although she feels fit, she is disturbed about the increase of weight, and she holds the paraffin responsible. The only other change in her habits during this period is the dropping of tennis, which she played twice weekly in summer, but not energetically. There is no evidence of glandular disturbance, and no treatment for the increased fat (which is generally distributed) has been given. I cannot conceive the possibility of the paraffin being responsible, unless through improved digestion following the marked improvement of the constipation, but should be glad to know if there is any evidence which would tend to convict the paraffin.

*** *This contrasts with the question of "P. C. P." in the Journal* of March 8th (p. 478), when the suggestion was made that such prolonged administration might inhibit growth.

MUSCULAR SPASMS IN STUMP AFTER AMPUTATION.

DR. R. O. C. THOMSON (Hucknall, Notts) asks for suggestions for the treatment of a man, aged 40, with an amputation through the thigh, the result of a gunshot wound during the war. He writes: The patient has attacks of spasmodic contraction of the rectus femoris, with twitching of the stump and spasms of pain. These attacks come on at varying intervals—sometimes weekly, sometimes after an interval of two or three months, and they last a varying number of hours. When the attack is at its worst, he has to hold the stump firmly to control its movement. I have tried morphine hypodermically; this eases the pain slightly, but does not produce sleep, and it leaves him feeling very ill and dizzy. Omnopon has the same effect. Allonal, luminal, and sedobrol (70 grains of bromide in four hours) have no effect. The after-effects of opium and morphine are too severe to justify its use.

SPECIFIC GRAVITY OF FAECES.

"M.B." (Hants) writes: Can anyone give me information as to the significance of the specific gravity of faeces? In a healthy child of 5 the motions occasionally sink like a stone in water; at other times they float normally. No medicines are being given, and the colour of the stools varies little, whether they float or sink.

NOISES IN THE HEAD.

"M. R." writes: A married woman, thirty-two years ago, after influenza, began to complain of noises in her head, chiefly musical, and sixteen years ago underwent a series of operations to drain infected nasal sinuses. She is now a mental wreck, owing to the increase in these head noises, describing them as being like machinery, hammering, train rushing through tunnel, screeching, etc. Three aural surgeons offer no further alleviation. I would be grateful for any suggestion as to treatment which might mitigate the intensity of her condition and so save her reason.

FLEA INFESTATION.

DR. K. M. ANDREW (Parkstone) writes: In a house similar to that described by "Pulex" (May 10th, p. 852) we entirely got rid of fleas by fumigating with paraform, which is, I think, more certain than spraying. After closing all windows, and hanging

a thick blanket over each fireplace, nine to twelve tablets of paraform should be placed on a tin lid over a spirit stove in each room. All bedding should be well exposed, and inside doors be left open; the spirit lamps are then lighted, and the house is locked up for an hour. The windows should then be opened, and the house may be comfortably lived in an hour later. The process may need to be repeated two or three times at intervals of three days or more.

INCOME TAX.

Upkeep of Medical Books.

"G. M. K." has in the past been allowed £7 per annum for "upkeep of medical books and instruments." He has now claimed £21, and has been asked by the inspector of taxes for an assurance that "it contains nothing in respect of additions of any description." What legal grounds are there for claiming that the cost of purchasing new books and instruments is allowable if incurred to keep the medical books and instruments up to date?

*** There is no judicial decision dealing directly with the point, though in 1926, in the case of Daphne *v.* Shaw, the High Court held that "depreciation allowance" could not be claimed on professional books. But it is a settled principle that a capital asset used for professional or business purposes can be maintained in reasonable working order at the expense of revenue, though improvements must be charged to capital account—that is, paid for out of taxed income. It is admittedly difficult to apply this rule to professional books and instruments. New editions or supplements bringing reference books already owned up to date are clearly allowable, as also the cost of professional journals, etc., and we are definitely of opinion that the cost of a book would be allowable if purchased to bring the library up to date, even though it was by a different author from that of the book already owned. On the other hand, the cost of the enlargement of the library by the purchase of more exhaustive treatises or those on additional subjects would not be allowable for income tax purposes.

Debenture Transactions.

"H. H." was one of the debenture holders on behalf of whom an action was taken to the House of Lords alleging that the purchase of the debentures was induced by misleading statements of the directors. The case was settled on the basis that each debenture holder received one-third the face value of his debentures. Should that amount be assessed to income tax?

*** The transaction appears to us to have been throughout of a "capital" nature, and we know of no grounds on which the amounts paid—practically in reduction of the original capital cost—can be assessed to income tax.

Allowance for Use of Own Premises.

"J. H. G." owns the house in which he lives and practises. Its value for income tax purposes is assessed at "£135" gross and "£88 15s." net. [The latter figure should perhaps be £108 15s.] He is allowed to deduct one-half of the rental value as applicable to professional purposes. On which amount should he base the deduction?

*** The correct basis is one-half of the *net* assessment, in which case, of course, that part of the annual expenditure on repairs, decorations, etc., which applies to the professional portion of the premises should also be deducted. The inspector of taxes may perhaps be prepared to allow one-half the £135 on condition that nothing is claimed for repairs, etc., but the former basis is more satisfactory as a rule.

Car Depreciation.

"A. C. R." sold a car in 1927, for which full obsolescence relief was given, and "more than wiped out the 1928–29 profits." Depreciation is therefore claimed for the first time as for the financial year 1929–30. On what capital value should it be based?

*** On the value as at January 1st, 1930; in accordance with a long-standing practice, which has judicial support, the rate of depreciation should be applied to the value as written down at the end of the last account year before the financial year for which the claim is made. "A. C. R." had, however, a claim—on the facts stated—to have the depreciation for 1928–29 calculated and carried forward for allowance against the first available year's profit. Strictly, such a claim should be made when the return is made for assessment, and it may be that the inspector of taxes will now refuse it as out of date. In that case nothing can be done at present, but the matter will be rectified when the next obsolescence claim is made in respect of that portion of the original cost not covered by depreciation allowances given and the amount for which the car is sold.

Use of Car: Appointment.

"T. G. B." uses his car for attending patients, though the Government department for which he acts would pay for the visits if he thought it worth while making claims. The car is used largely for private purposes. Can he claim any allowance for the use of his car?

*** The statutory rule provides for the allowance of expenses incurred "wholly, exclusively, and necessarily in the performance of the duties of the office." It seems impossible to convince the taxing authority of a Government department that the use of the car is "necessary" if the regulations contemplate some other means of transport, or would enable the taxpayer to obtain a grant for the expense. The expense of new books would, we consider, be allowable to the extent necessary to maintain up to date such a reference library as is reasonably required to carry out the duties.

LETTERS, NOTES, ETC.

MATERNITY AND CHILD WELFARE IN HUNGARY.

THE Stephania National Association for the Protection of Mothers and Infants functions in Hungary. As a compliment, perhaps, to this country the managing director, Mr. Louis Keller, has published his last annual report in what may be described as broken English. In Hungary, it appears, "the situation of the protection of mothers and infants is the most disadvantageous among all kinds of social work." Whereas in Western countries the visiting nurse may be sure that the advices given will be kept by the mother, in Hungary "house dogs will be set on her, and she will need the painful work of certain mouths to obtain the first result. . . . Additional efforts will be necessary to convict mothers from the good influences of cleanliness, fresh air, and of the sun." However, Mr. Keller hopes that by "sistematical work and constant, further progeress" will be reached. As the Stephania Association only began its work in 1921 it is hardly to be expected that its activities should have had much effect, as yet, on infant mortality rates. But Mr. Keller produces figures to show a difference in rate to the advantage of territories in which dispensaries have been established; and "plaids for an incerase of their number." He notes, however, that "opinions are audible that we are too poor for spend so much money for the protection of mothers and infants"; and, setting aside the "charitative duty," proceeds to analyse this proposition from the economical point of view. Pathetically estimating the value of a Hungarian baby at only one-twentieth the value of an infant in Amerika, he shows that the death of one baby represents a damage "expressed in money of 500 pengös in average." Taking into consideration the diseases prevented by the protection of mothers and infants, and the control obtained in tuberculosis, syphilis, and alcoholism, Mr. Keller estimates the value of the work to the community at 750 pengös, as opposed to the 500 pengös (of which the State contributes half) spent on each infant. In fact, in his opinion, the protection of mothers and infants "refunds the expenditures spent for, and gives a profit of 50 per cent." To complete the work, however, "we hawe to create, in accordance with the necessities arisen, and with the possibilities given, the half closed and closed institutes for the protection of mothers and infants in all places." These cryptic institutes suggest that, as with our own social reformers, the limit of expenditure in Hungary has not yet been reached. The report then sets forth the methods of administration and propaganda, in which our own method of including a "yearly one festival for the propaganda of the ideals" seems to be followed. We note, however, that there is a "sollicitor's office," which intervenes at divorce court, for aliment for children, for legitimation, and in other affairs. The organization is provided, also, with a home for mothers, a central laboratory, a central dispensary, a central milk kitchen, and a State nursing boarding school. As it also provides "sommer holydays for children" and "quartz treatment," it would appear that Hungary has gone some way in the direction of the late Professor Wynne's ideal of reducing voluntary societies from three hundred to three. Considering the extent of ground covered by the activities of the Stephania National Association, we think that Mr. Keller is too modest in pleading the low cultural level of his country. We wish him and his country every success in their efforts, so that even the house dog may give a friendly greeting to the nurse.

MEDICAL GOLF.

THE summer meeting of the Shropshire Medical Golf Association was held at Church Stretton on Sunday, May 25th, by courtesy of the committee of the Church Stretton Golf Club. The competition results were as follows:

Shropshire Medical Challenge Bowl.—Dr. T. R. Elliott and Dr. K. M. Rodger, 71; Dr. J. Lavelle, 73; Mr. A. D. Haydon, Dr. Clarke, and Dr. J. C. Davis, 75; and Dr. A. J. Ireland, 79.

Foursomes v. Bogey also resulted in a tie: Drs. J. A. Ireland and T. R. Elliott, and Mr. A. Lavelle and Dr. Harker—1 down.

The next meeting of the association was fixed for the second Sunday in October at the Wrekin Golf Club.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 38, 39, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 243.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

439. Meningitis due to B. enteritidis.

F. B. LYNCH and S. A. SHELBURNE (*Amer. Journ. Med. Sci.*, March, 1930, p. 411) record a fatal case of *B. enteritidis* meningitis in a female infant aged 12 months, and have collected 15 other cases from the literature, 4 of which occurred in Germany, 3 in Italy, 2 in Austria, 2 in Britain, 2 in France, 1 in Syria, and 1 in the United States. The ages of the patients ranged from 11 days to 25 years. The cerebrospinal fluid was purulent in 10 instances, clear in 4, and in one its nature was not reported. Blood cultures were positive in all cases in which they were made, except in the case of the present authors. The duration of the meningeal symptoms in the fatal cases ranged from one to fifteen days, most of the deaths occurring within the first week. All the children under the age of 1 year died, and all the eight cases which came to necropsy had purulent meningitis, while five patients had enteritis and one pyelitis.

490. Prophylaxis of Scarlet Fever.

F. M. MEADER (*Journ. Amer. Med. Assoc., March 1st, 1930*, p. 622) treated 450 contacts with scarlet fever by injection of 7.5 c.cm. each of the pooled serum from donors who had had scarlet fever within a year or a little earlier. The serum was given to the contacts within six months from the time it was drawn. The subsequent history of the contacts who had been injected showed that 2.9 per cent. developed scarlet fever, as compared with 12.8 per cent. in a similar group of contacts who did not receive the serum. The immunity did not last longer than three or four weeks. Meader regards the method as particularly valuable for young children who have been recently exposed to scarlet fever, and also for the infirm. It was found useful in checking outbreaks of scarlet fever in hospitals and other institutions.

491. Non-gonorrhoeal Urethritis.

A. KRISTJANSEN (*Ugeskrift for Laeger*, March 20th, 1930, p. 276) warns against labelling cases of urethritis as gonorrhoeal merely on the strength of the clinical picture, however typical this may seem, and even when such complications as conjunctivitis and arthritis appear. In the past a negative bacteriological examination in such cases has too often been discounted, but the complement fixation *test may be decisive. The author records a small epidemic* which began with a girl, aged 16, suffering from a vaginal discharge stated to have existed for two years. She was treated in hospital with irrigations for a couple of months, chronic gonorrhoea being diagnosed, although gonococci could not be found. A man infected by her developed a urethritis which lasted three months, but was followed by no complications, and microscopical examinations failed to reveal gonococci in the discharge. In another contact admitted to hospital for gonorrhoea and gonorrhoeal ophthalmia, the last coitus had been in the first half of December, 1928. On January 12th, 1929, he noticed a yellow discharge from the urethra, and on January 20th had sore throat, fever, and a purulent discharge from the conjunctivae associated with photophobia. He also complained of pain, tenderness, and oedema in the left knee-joint, left fifth metatarso-phalangeal joint, and the right first metatarso-phalangeal joint. Erosions, partly confluent, on the soft palate and the inside of the right cheek were covered by a yellow pseudo-membrane. Under large doses of salicylates the articular manifestations disappeared in six weeks, but for a considerable time the temperature remained slightly raised in the evening. The ocular symptoms diminished after a few days' treatment with a 10 per cent. solution of argyrol, and they had disappeared completely and without leaving any permanent injuries when the patient was discharged. The urethral discharge was examined microscopically twelve times, and the conjunctival discharge eight times, without gonococci being found; nor were they recovered from cultures on ascites agar. Five complement fixation tests for gonococci performed at different stages of the infection were completely negative, as was also the Wassermann test.

492. A. CASTELLANI (*Urol. and Cut. Rev.*, March, 1930, p. 147), who records three illustrative cases, states that non-gonorrhoeal urethritis, though not of frequent occurrence, is not so exceedingly rare as some authorities suppose. The following three groups are described: (1) those of traumatic *origin; (2) those of protozoal and metazoal origin; and (3)* those of mycotic origin. Traumatic urethritis is exceedingly rare, but is occasionally found in soldiers and porters doing long marches day after day. As regards the second group, several of these are doubtful, while the flagellates and some of the other protozoa found are probably not the true causative agent. Mycotic urethritis, which is the most important from the practical point of view, may be classified etiologically according to the botanical position of the fungi observed, or clinically according to the colour of the discharge, into three subgroups: (1) urethritis with black discharge, which is usually associated with yeast-like fungi (monilia, cryptococcus, saccharomyces); (2) urethritis mostly associated with the presence of cladosporium, aspergillus, and penicillium; and (3) urethritis associated with red pigment-producing yeast-like fungi together with red pigment-producing cocci. All the protozoa and fungi found in non-gonorrhoeal urethritis in the male have also been found in vaginitis and vulvo-vaginitis, so that it is not improbable that these infections may be transmitted by sexual intercourse.

493. Tularemia in Norway.

T. TRJÖTTA (*Nordisk Medicinsk Tidskrift*, March 22nd, 1930, *p. 177) observes that though about 800 cases of tularemia* have been diagnosed in America up to September, 1929, this disease has escaped detection hitherto in Europe, with the exceptions of Norway and Russia. He is, however, convinced that it exists in every country where the carriers of this disease—the tick, the fly, and the hare—are to be found. He has already diagnosed, clinically and serologically, 11 cases in Norway, and several other cases, which he has not hitherto been able to examine serologically, have been notified to him. His first three patients had been shooting hares in the country. The fourth was a kitchen-maid who, with five other maids, had dressed 130 hares. The fifth patient was one of these other maids. The next five patients were employed in a shop selling game. The eleventh and last patient was a housewife, who dressed a hare on January 21st, 1930, and who, in the evening of January 23rd, noticed a tender lump under her left arm; next morning there was a red spot on the back of her left thumb. She suffered from attacks of shivering, lost her appetite, and felt feverish. She was admitted to hospital on February 20th, and an abscess as large as a tangerine orange in the left axilla was evacuated. In addition to the five cases [illegible] there were several other members [illegible] o had previously presented similar [illegible] ran a lighter course in the game dealers than in the game hunters; and this may have been so because the latter, when gutting hares, are in contact with the virus in a comparatively fresh state. Game dealers, on the other hand, are liable to be infected with the virus, which has become attenuated by the low temperature under which game is conveyed to a town. The author has not yet seen a case of tularemia conveyed by rats, as observed in Russia. He knows of no other prophylactic measure than that of the wearing of rubber gloves when hares are handled. As for the treatment of these cases, he passes on the recommendation that swollen lymphatic glands should never be incised before they have softened completely and the pus is close to the surface; incision of a hard lymphatic gland may prolong the disease.

Surgery.

494. Congenital Dislocation of the Wrists.

A. CSERNY-PECHANY (*Zentralbl. f. Chir.*, March 29th, 1930, p. 774), who records two illustrative cases, one in a woman aged 47, and the other in a girl aged 18, remarks that the questions of the etiology and treatment of Madelung's disease (congenital dislocation of the wrists) are by no means settled. As a general rule the condition is bilateral, like congenital malformations of the forearm, such an absence of the radius, hypoplasia of the ulna, congenital dislocation of the radius, and constitutional lesions of the epiphyseal cartilages (Perthes's disease, Köhler's disease, and Schlatter's disease). Madelung's disease has been variously attributed to familial predisposition (Siegrist, Melchior, and Reich), rickets or late rickets (Brandes, Bassini), or trauma. In the present author's first case there was evidence of rickets, but not in the second. Neither showed any familial predisposition. Both, however, suffered from irregular menstruation, indicating a disordered ovarian function, with which the disease

is probably connected. Another argument in favour of this view is the fact that the disease occurs in the great majority of cases at puberty or just before. In the literature at his disposal the author has been able to find examples only in the female sex. *Reich has published a genealogical tree* in which the bilateral deformity was found in female members of the family in three generations. In further support of an etiological connexion between ovarian function and Madelung's disease is the well-known effect of ovarian function on the growth of bones, as shown by the sudden increase in height at puberty. Lastly, it has long been known that osteomalacia can be cured by oöphorectomy. On the strength of these considerations the present author tried subcutaneous injections of ovarian extract, with the result that the disease was arrested in one case and decided improvement took place in the other.

495. Embolectomy of Left External Iliac Artery.

E. DAHL-IVERSEN (*Lyon Chir.*, January–February, 1930, p. 39), points out that whereas embolectomy of the pulmonary artery is an unusual operation, owing to the difficulty of diagnosis and the probability of the sudden death of the patient, embolectomy of the arteries of the limbs is fairly common and gives a good chance of recovery if performed early. A case is reported of a woman, aged 53, admitted to hospital with phlebitis. She had great pain and a feeling of heaviness in the right leg; there was also tenderness and infiltration along the veins in the lower part of the thigh. Two days later phlebitis started over the left internal malleolus; this was followed in four days by violent pain in the left leg, which was pale and cold from below the knee, particularly in the foot and lower part of the calf. Movement was not possible in the toes, and the leg could not be raised. Examination of the artery disclosed the absence of pulsation in the foot and in the lower part of the leg, but a feeble pulsation could be felt in the upper part of Scarpa's triangle. After careful consideration a diagnosis was made of an embolus in the femoral artery, and immediate operation was ordered. A femoral arteriotomy was performed by an incision in Scarpa's triangle; the fascia was divided, the muscle drawn outwards, and the vessel, which was found to be without pulse or blood, was exposed. The artery was opened after temporary ligature, and the embolus, which was 12 cm. long, was removed. The incision was then closed by paraffin sutures, the instruments and swabs being soaked in a citrate solution. There was no haemorrhage from the line of suture, and pulsation in the artery was immediately seen. The skin incision was then closed, and pulsation in the foot was restored, the limb regaining its normal colour. Examination of the embolus showed it to be cylindrical in shape and composed of a typical thrombus; it had evidently been formed in a vein from which it had become detached and had passed through a patent foramen ovale. The patient made a good recovery after the operation.

496. Treatment of Glandular Epitheliomata.

S. LABORDE, R. HUGUENIN, and F. AMAN-JEAN (*Bull. de l'Assoc. Française pour l'Etude du Cancer*, January, 1930, p. 15) quote two cases as illustrating that glandular epitheliomata respond to radium treatment in the same way as *do true epitheliomata of the skin. The first case* was a woman of 51, operated on in 1924 for cancer of the breast with glandular involvement; there was no post-operative radium treatment. Four years later ulceration developed, the area being as large as the palm of the hand when the patient was seen in 1929. Histologically the condition was undoubtedly a glandular epithelioma. Radium treatment was given, the technique and dose being analogous to those used in the treatment of epitheliomata of the skin. Complete cicatrization from the periphery inwards was effected in several weeks, and the area remained healed. The second patient was a woman, aged 52, who had intestinal haemorrhage and trouble in defaecation for two years. On examination the whole anal canal was invaded by growth. The anal margin was covered by a vegetating ulceration stretching 4 to 5 cm. each side of the anal orifice. The tumour was fixed and inoperable, and was found to be a cylindrical epithelioma, definitely glandular in type. Treatment with radium was given both internally and externally; after eight days the haemorrhage ceased and there was progressive cicatrization of the skin, although the growth remained. Three months later a metastatic nodule in the perineum required further treatment. By this time complete cicatrization of the ulcerated area had occurred. The authors remark that it would be reasonable to suppose that cancer cells which have migrated from the primitive tumour to develop in a different tissue retain their initial radio-sensibility or radio-resistance. As the authors indicate, development in a tissue which is not the natural habitat of the tumour apparently modifies the reaction to radium emanations.

Therapeutics.

497. The Use of Bacteriophage Filtrates.

WHILE agreeing that bacteriophage therapy is by no means a panacea, and that its applicability should not be exaggerated, T. B. RICE (*Amer. Journ. Med. Sci.*, March, 1930, p. 345) reports 300 cases of suppurative conditions treated by the local application of bacteriophage filtrates, and concludes that this method of treatment has a definite value; it is uncertain how the reagent acts, apart from increasing phagocytosis and liquefaction. He thinks that stock preparations are apparently as good generally as those specially prepared. The dosage does not seem to be important provided that enough of the filtrate is used to give good contact as a wet dressing. No bad results were observed, and no evidence was obtained of the development of resistant strains which were more pathogenic than the original one. Rice thinks that strong antiseptics are contraindicated during bacteriophage therapy, but he has no definite evidence that they would have altered his results. Of 66 cases of boils and carbuncles so treated, excellent results followed in 55, moderately good in 5, failure in 5, and one case was untraced. At least four of the failures were explainable, since the organism concerned—a staphylococcus in two cases and a resistant staphylococcus in the other two—was not susceptible to the bacteriophage strains at the author's disposal. Excellent results were obtained in 24 out of 27 cases of abscess, the bacteriophage being injected into the cavity, or passed through a catheter into deep lesions. Particularly good results were obtained by injecting the filtrate suspended in a 1 per cent. agar jelly, when the cavity permitted this preparation to leak out easily. Other conditions which responded satisfactorily were: staphylococcal cellulitis and purulent arthritis, appendix abscess, faecal and urinary fistulae, cystitis, infected wounds, bedsores, perineal lacerations, and pustular acne. The presence of dead bone caused the treatment to fail. The preparation employed for the most part was a mixture of various filtrates representing several cultures of the staphylococcus and *B. coli*, with the same number of the homologous bacteriophage strains.

498. Benzo-meta-cresol in Intestinal Infestations.

A. SCHWARTZ, A. AZAM, and M. YOVANOVITCH (*Presse Méd.*, April 9th, 1930, p. 485) point out that, though many anti-parasitic medicaments, such as the cresols, are powerful parasiticides and germicides, yet considerable danger attends their use owing to their toxicity. After numerous experiments with various combinations of thymol and cresol in order to find one which retained the efficacy of these drugs with a lessened toxicity, these workers finally discovered two substances, cinnamic and benzoic combinations with cresol—namely, cinnamo-cresol and benzo-meta-cresol (cresentyl); the second compound is strongly advocated. This drug is prepared by the action, aided by heat, of benzoyl chloride on strictly pure meta-cresol. The product thus obtained is washed with a dilute solution of soda, and purified by several crystallizations in alcohol at 90° C. Chemically pure benzo-meta-cresol is a white, crystalline substance, melting at 54°, insoluble in water, but soluble in alcohol, ether, benzine, chloroform, and *fatty acids*. Its toxicity is *nil*, and it is well tolerated by children as well as by adults. The action of this medicament is most remarkable and constant in tricocephalosis and intestinal amoebiasis, and also in lambliasis if there is no infestation of the gall-bladder; it is also an excellent intestinal antiseptic. Its anti-oxyuric action is not so marked. The usual daily dose is 4 to 5 grams for adults and 2 to 3 grams for children, given *fasting in the morning for four or five days* in fractional doses of 1 to 1.5 grams every half-hour. Three or four such series at intervals of six days generally suffice to rid the system of the parasites. As an intestinal disinfectant, the daily adult dose is 2 to 3 grams (in fractions of 1 to 1.5 grams), in children the dose is 1 to 2 grams according to age, and in infants 0.5 to 1 gram. These doses should be given half an hour before each meal for eight to ten days; several such courses at intervals of a week are advised.

499. Congo Red as a Haemostatic.

SINCE experiments on animals have shown that injections of neutral dye solutions altered the blood coagulation time, J. BECKER (*Münch. med. Woch.*, March 7th, 1930, p. 396) tried the effect of intravenous injections of 10 c.cm. of a 1 per cent. solution of chemically inactive Congo red in a number of cases of recent haemorrhage due to various causes. The coagulation time, estimated at intervals after the injection, was diminished and the number of platelets was increased. Becker therefore considers that Congo red may be of definite value as a haemostatic.

Neurology and Psychology.

500. Psychical Factors in Organic Nervous Disease.

MANY nervous patients are encountered who present no objective findings to account for their complaints, and are designated and treated as non-organic, functional, hysterical, etc. Many of these return after varying periods with undoubted evidences of organic nervous disease, which can be readily correlated with the original complaints. From their clinical experience with some of these cases, A. M. RABINER and M. KESCHNER (*Journ. Neurol. and Psychopath.*, April, 1930, p. 311) suggest that the evolution of some organic nervous diseases may occur in two phases: an early psychical phase, and a later organic one. The transition between these two phases may be almost imperceptible, being only detected after prolonged observation by the same observers; and during this transition there may occur structural changes in the nervous system resulting from disturbances of function during the first or non-organic stage. Not only may structure affect function, but also function may influence structure. The increase in the size of cells of hypertrophied muscles and hyperfunctioning glands, the physiological development of nerve tracts shown by Kappers to exist during increased activity, and the effect of hypofunction or afunction on morphology as illustrated in retrograde degeneration are cited in support of this assertion. Moreover, Cassirer has stated that every dysfunction, whether due to a disturbance in the afferent or efferent path, or in the processes supposed to exist between them, leads to an anatomical change in the structure of the nerve cell. Modern researches seem to point to abnormal lipoid metabolism as a genetic factor in the production of degenerative lesions in the central nervous system; and the hypothesis is advanced that psychical factors may, through the sympathetic nervous system, affect lipoid metabolism and so bring about structural changes in the central nervous system at the basis of the organic clinical pictures. Three cases are cited in which the patients, following psychical trauma, developed motor disorders that did not conform to any known organic nervous disease. Later there appeared signs of organic nervous disease, undoubtedly due to structural changes in the nervous system.

501. Acute Ascending Paralysis of Landry.

ACCORDING to C. F. READ, T. E. CONLEY, and H. H. CONLEY (*Journ. Amer. Med. Assoc.*, February 22nd, 1930, p. 557), opinions vary considerably concerning the pathology of Landry's syndrome (ascending paralysis of predominantly motor type), and there is considerable doubt, during life at least, about its pathogenesis and the anatomical regions involved. It would seem impossible to designate before death how and to what extent the lower motor neuron is involved or what cord changes are taking place, especially in the absence of an epidemic of poliomyelitis. A case is reported in a man aged 23, the typical age for this affection, which was unrelated to any other disease except an indefinite gastro-intestinal disturbance (in the absence of any epidemic); it ran a classic course of progressive, flaccid paralysis without sensory manifestations. It presented the unusual feature of continuous manual artificial respiration being required for over four days, with final bulbar death. In this patient the onset was marked by pain in the abdomen, obstinate constipation, and abdominal distension, together with weakness and dyspnoea; these symptoms had developed in the order named during thirty-six hours. Cyanosis ensued and artificial respiration was instituted. Neurological examination revealed apparent bulbar palsy, only slight movement of the soft palate and uvula, with protrusion of the tongue to the labial margin, difficult swallowing, and a whispering voice. The pupils, and the third, fifth, and seventh cranial nerves, were normal. There was paralysis of the phrenic and intercostal nerves. The arms, hands, and fingers could be moved weakly, and the tendon reflexes were absent. There were no signs of atrophy. The lower extremities showed a complete flaccid paralysis with entire absence of tendon reflexes. The corneal and plantar were the only superficial reflexes obtained. Sensation for position, touch, and pin-prick was unimpaired, and there was no complaint of pain at rest or when the limbs were manipulated. Retention of urine was present, with slight stiffness of the neck and a bilateral Kernig sign. The patient died of cardio-respiratory failure on the seventh day. On microscopical examination the cord showed throughout perivascular infiltrations, especially in the grey matter. The infiltrating cells were mainly lymphocytes, with plasma cells and polyblasts. The blood vessels were also greatly engorged; in many places very large haemorrhages were present. The ganglion cells were swollen and showed chromatolysis and neurophagia. There was proliferation of the glia cells in both the grey and white matter, and in many instances nodules were formed, especially in the medulla. These changes, though prominent in the medulla, were not as marked as in the cord. The meninges were but slightly involved; the roots were infiltrated by haematogenous elements, the perineural spaces being especially involved.

502. Basal Metabolism and Emotional States.

G. W. HENRY (*Journ. Nerv. and Mental Dis.*, December, 1929, p. 593) remarks that during the past twenty-five years considerable evidence has been accumulated which indicates that a personality disorder is really a psycho-biological reaction, and that the biochemical component is constant though not readily demonstrable. The relation between highly painful emotions and the adrenaline-sugar content of the blood has long been known; and in the acute psychotic disorders accompanied by intensely painful emotions there is a tendency towards hyperglycaemia and a definite retardation of the gastro-intestinal motor functions. There seems to be an increased calcium and phosphorus content of the blood in manic conditions, while there is a relative decrease of these substances in tense, agitated, depressed states. Localized pallor or flushing associated with different emotional conditions is commonly noted, and cold perspiration and cyanosis of dependent parts are recognized as a frequent accompaniment of acute schizophrenic disorders. With regard to basal metabolism studies, there are still no definite conclusions concerning the variations in the relative amount of energy consumed in the maintenance of automatic functions and body heat in personality disorders. Henry records the result of a study of the basal metabolism in emotional states, in which most of the patients tested were in an acute phase of mental disease but were able to co-operate in the requirements of the tests. The following conclusions seem justified from this study. A definite relationship exists between basal metabolic processes and emotional states regardless of the type of personality disorder. Elated, over-active, and talkative states are accompanied by accelerated basal metabolism, while in depressed, under-active, and under-talkative conditions it is retarded. Apprehensive, tense, and agitated states usually imply an accelerated basal metabolic rate, but this may be counteracted in cases of intense depression. A retarded rate is present in apathetic states, but the retardation is not as great as in depressed conditions. Some of the apparent variation in the metabolic rate may be due to the different emotional states of the tested subject. The rate may be altered to a pathological degree with no other apparent factor than an unusually intense emotional state, and therefore the interpretation of the rate in any given case requires consideration of the prevailing emotional state of the individual tested.

Obstetrics and Gynaecology.

503. Uterine Fibromyoma.

F. W. LYNCH (*Journ. Amer. Med. Assoc.*, January 18th, 1930, p. 156) discusses uterine fibromyoma, basing his observations on a series of 683 cases. All tumours larger than 1 cm. in diameter were included in the compilation, and any fibroid mass was classified as large which, together with the uterus, exceeded the size of a four months' pregnancy, growths of this extent being too bulky for treatment with radium. Using this criterion 394 cases were classified as large, and 289 as small. The age of the patient has an important bearing on the choice between surgery, radium, and x-ray treatment. Examination of the past histories of the patients disclosed the fact that they had previously undergone an exceptional number of surgical operations on the genital tract and elsewhere in the body, and it would seem that women in whom uterine fibroids develop have had for some time uterine and thyroid tissue of less than the average normal degree of healthiness. Haemorrhage was the main symptom in only one-third of the cases, but it was present in 85 per cent. of all submucous growths, though not confined to these only. The large tumours grew rapidly as a rule, and appeared to give rise to symptoms earlier. The incidence of sterility in women with fibroids is 23.3 per cent., and may be due to congenital causes rather than to the presence of the tumour; the incidence of malignancy was 4.6 per cent., there being 32 cases in the series of 683. Lynch concludes that each method of treatment has its merits, and all have their limitations; fibroids which cause symptoms may be treated with a comparatively low mortality. It appears that in an abnormally high percentage of these cases the pelvic structures generally are in an unhealthy state. Even though most of the patients had never resided in goitre belts there was a striking frequency of goitre in the series, and this is held to warrant a belief that a relationship exists between

goitre and fibroids. Diabetes was present in eight cases, a complication which has led the author to hesitate before operating, however much the condition may have been improved by insulin.

504. Rectal Examinations in Labour.

R. T. LAVAKE (*Minnesota Med.*, February, 1930, p. 110) supports the view that rectal examinations during labour are less productive of post-partum rise of temperature than vaginal examinations. The work of Kronig, confirmed by Whitridge Williams, and later by Hjalmar Bergholm, indicates that the vagina of every pregnant woman who has not been examined can be considered aseptic unless gonococci are present. Thus, with good pre-natal care, every woman should begin labour with an aseptic vagina. The author believes that rectal examinations employed during labour instead of vaginal ones will maintain this aseptic state. He quotes comparative figures by Jegge: of 500 cases rectally examined, pyrexia developed in 6 per cent., while of 500 cases vaginally examined, pyrexia ensued in 11 per cent. Other figures quoted are those of Guggisberg, who cites 4,642 cases examined vaginally with 0.12 per cent. deaths from sepsis, and 17.5 per cent. febrile cases (temperature of 99.5°); this compares with 3,010 cases examined rectally with no deaths from sepsis and 11 per cent. febrile cases. LaVake maintains that each year's experience has added to his own conviction that in all types of situations and conditions the rectal examination is potentially the safer. In addition, he emphasizes the fact that the use of this examination among educated people reassures the patient and her family that all possible sources of infection are being avoided. He finds that the greatest potential danger resident in the rectal examination is the possibility of overlooking what has been called the concealed second stage of labour. The cervix may be completely dilated, although the rectal examination gives the impression of incomplete dilatation. When this possibilty is borne in mind, however, any doubt can be confirmed by an aseptic vaginal examination.

505. Thymus and Pituitary Extracts in Labour.

J. JARCHO (*Amer. Journ. Obstet. and Gynecol.*, January, 1930, p. 81) records briefly his views on the uses of thymophysin (a mixture of thymus and pituitary extracts) in labour. He reports the conclusions of such European workers as Temesváry, Jahreiss, and Graf among others, who agree as to the great value of thymophysin in labour, especially in the first two stages whenever the uterine pains are weak. These pains are rendered more rhythmic and more powerful than with pituitary extract alone; their action lasts longer and they shorten labour considerably. The action of thymophysin continues through the third stage, preventing the development of secondary uterine inertia and hastening expulsion of the placenta. Haynes has used thymophysin successfully in 31 out of 34 cases of primary and secondary uterine inertia. Jarcho reports his own results in 18 cases; the uterine contractions were rendered more rhythmic and more powerful, the pains continued longer, cervical dilatation was aided, and the first stage was shortened. He agrees that the potency of thymophysin persists through the third stage, the placenta being expelled usually in from fifteen to twenty minutes with no excessive haemorrhage. On examining the blood of mother and child no change was found in the platelets, the red and white cells, or in the coagulation time. In cases where the blood pressure was not already high there was often a temporary rise of 5 to 20 mm. of mercury, followed by a fall. In no instance was there any ill effect to mother or child. Temesváry, it is added, now uses thymophysin in normal labours, and by so doing claims to shorten labour by five to ten hours. Jarcho gives 0.5 c.cm. intramuscularly, followed by a second similar dose, or even one of 1 c.cm., if the first injection proves ineffective.

Pathology.

506. Changes in Humoral Immunity during Experimental Pneumococcal Infection.

E. E. TERRELL (*Journ. Exper. Med.*, March, 1930, p. 425) infected dogs and cats with virulent Type I or II pneumococci, the organisms being injected intrapleurally or intraperitoneally, or by intrabronchial insufflation. Blood was withdrawn before the animal was infected, and on each day subsequently; blood cultures and plate counts were taken in most cases, and the serum was tested for its opsonic and its pneumococcidal promoting properties, using the methods described by Robertson and Sia. It was found that with an overwhelming infection, accompanied by early blood invasion, there is a rapid decrease in the concentration of humoral immune bodies; these disappear entirely by the time of death. In non-fatal cases of severe generalized infection the same early diminution of humoral antibodies occurs, but the concentration of immune bodies begins to rise with the onset of recovery about the fourth day. These immune bodies are acquired as the result of infection. The diminution in the normal antibodies during the stage of infection appears to be due to their combination with the soluble specific substance formed by the pneumococci. When infection is confined to the lungs and pleura, the concentration of antibodies often remains about normal throughout the disease, and the animal may die of the local disease with a negative blood culture. According to the author, these results suggest that, after infection of the dog or cat with pneumococci, the chief function of the natural anti-pneumococcal substances in the blood is to prevent or limit blood invasion. When the infection is localized to the lungs, these circulating antibodies appear to have little effect either in preventing the spread of the process locally, or in determining the outcome of the disease.

507. Scarlet Fever Dick Toxin.

R. LOPATIZKI (*Jahrb. f. Kinderheilk.*, January, 1930, p. 241), as the result of experiments on rabbits and observations on children, comes to the following conclusions. The Dick toxin consists almost exclusively of exogenous bacterial toxins which pass over nearly completely into the surrounding nutrient medium and produce the Dick reaction. In addition to these toxins there is a very insignificant amount of endogenous toxin present which is firmly attached to the bodies of the bacteria, passes over on maceration into the solution, and in exceptional cases, such as very susceptible individuals, or possibly those with a special diathesis, may produce a very weak Dick reaction. On immunizing rabbits with the bodies of scarlatinal streptococci grown on plain agar and blood broth, and then carefully washed free from all free toxin, serums were obtained which did not produce a Dick reaction. Ehrlich's multiple law is applicable to Dick toxin, which is a toxin *sui generis*, possessing a vasomotor character, and in many respects subject to the laws of true toxins.

508. The Sedimentation Rate during the Climacteric.

O. BACH (*Ugeskrift for Laeger*, March 27th, 1930, p. 305) has investigated the sedimentation rate of the erythrocytes in 73 women between the ages of 40 and 60 in attendance at the Silkeborg hydropathic establishment in Denmark, but not suffering from any ailments other than those commonly associated with the climacteric. The rate was 11 mm. or less in 33 cases, 11 to 20 mm. in 24 cases, and more than 20 mm. in 16 cases; it was thus above the normal in 54 per cent. of all the cases. Bach is therefore inclined to regard the climacteric as a condition which in itself may affect the sedimentation rate to such an extent as to diminish its diagnostic value in relation to ailments other than those of the climacteric. The technique he adopted was that elaborated by Westergren, the readings being taken after an hour.

509. Vaccination of Monkeys against Poliomyelitis.

C. P. RHOADS (*Journ. Exper. Med.*, January, 1930, p. 1) inoculated four *Macacus rhesus* monkeys with 16 c.cm. of a 5 per cent. suspension in saline of glycerolated spinal cord of a mixed poliomyelitis strain. The inoculum was given intradermally into several sites, evenly spaced blebs about 0.5 cm. in diameter being produced. No symptoms of poliomyelitis occurred during the succeeding month. The serum of the animals was then tested for its power to neutralize the virus. A mixture of serum and virus was injected intracerebrally into a normal monkey, while a control monkey was injected with a mixture of normal serum and virus. The results showed that the serum of each of the four vaccinated monkeys was able to neutralize the virus, whereas the normal serum was unable to do so. The four vaccinated monkeys were then inoculated by the cisternal route with about five lethal doses of virus filtrate, a normal monkey being used as a control. One of the vaccinated monkeys died of intercurrent disease. Of the remaining three, two developed no symptoms of disease, while the third developed typical poliomyelitis but recovered. The control monkey died of poliomyelitis in six days. The author concludes from this small series of tests that it is possible by the use of a single large dose of active virus, distributed over a number of sites, to produce an active immunity to poliomyelitis in monkeys. It is of importance that the inoculum should be introduced at a single sitting; if it is distributed over a number of days—that is, if repeated small intradermal injections are given—the animals develop preparalytic symptoms, and may actually succumb from typical paralysis.

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

ASPIRIN DERIVATIVES

THE HARROGATE FANGO

THIS recently discovered natural mud now takes the place of and compares very favourably with previously imported foreign muds. It possesses the essential properties—chemical, mechanical, and thermal—which make the "pack" treatment so effective for local application.

There is an acceleration of blood flow to the affected part, with increased metabolism and both diuretic and diaphoretic excretion.

Beneficial results are to be anticipated in cases of Rheumatic diseases of the Joints, Muscular Rheumatism, Neuritis, Chronic inflammatous conditions of the Gall Bladder, and certain diseases of the Liver.

Pullman and Fast Restaurant Car Trains daily from King's Cross Station, London.

For full details and complimentary facilities apply to F. J. C. Broome, General Manager, 3, The Royal Baths, Harrogate.

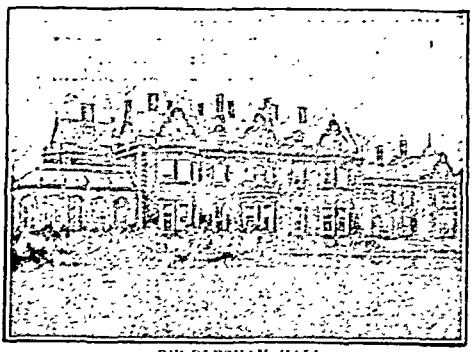
THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.



Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16. *(Toll Call from London.)*

ALCOHOLISM, DRUG HABIT, NEURASTHENIA, etc.

BAY MOUNT, PAIGNTON.

ESTABLISHED 1922. *'Phone:* PAIGNTON 5110.

A comfortable, private HOME, charmingly situated, overlooking Torbay, near Torquay. Main line, 3½ hours from Paddington. Both Ladies and Gentlemen admitted as voluntary patients. The treatment is the outcome of many years' experience, and besides removing all craving for drink or drugs, it has a tonic action on the system and the general health is improved. Alcohol and drugs reduced gradually, without suffering.

FUNCTIONAL NERVOUS DISEASES AND NEURASTHENIA are also treated with excellent results. Cases with insomnia, depression, etc., do especially well.

Exceptionally good climate and ample and varied amusement. Moderate, inclusive terms, Prospectus, etc., from STANFORD PARK, M.B., Ch.B., Res. Med. Supt., Bay Mount, Paignton.

INEBRIETY

DALRYMPLE HOUSE, RICKMANSWORTH, HERTS.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

BELVOIR NURSING HOME,

for hundreds of years have proved beneficial for gout, rheumatism, sciatica, nerve troubles, etc. Rejuvenation; all modern curative methods, Sport, Mountain Railway, Beautiful woods. 23,000 guests.

Information from the "Badeverwaltung" or "Kurverein."

EXCELLENT TROUT FISHING.

SWISS SPAS.

BADEN.

On the main line Zurich-Basle and Zurich-Berne. The hot springs of Baden were already known to the Romans. 17 radio-active wells at a temperature of 113.4°F. They contain sulphur and sodium chloride. The baths are obtainable in the hotels themselves. Treatments: *warm baths, shower baths, massage, electric baths, inhalation,* drinking cure, diagnostic-therapeutic institute, mechanotherapy. Recommended for metabolic diseases, rheumatism, gout, sciatica, diseases of the muscles, bones, and joints, retarded convalescence after injuries and operations.
Season: April 1st to November 1st.
For information apply to: Spa Director, Baden, Switzerland.

LOÈCHE-LES-BAINS.

One hour by electric railway from Loèche (main station on the Simplon route). Mild alpine climate. The baths were already known to the Gauls and Romans. The radio-active springs contain chiefly sulphate of lime. Two swimming pools. Every hotel has its own bathing installation. Treatments: warm baths, douche-massage, injections, air and sun baths. Recommended for: gout, rheumatism, sciatica, anæmia, post-operational conditions, convalescence, gynæcological diseases, circulatory disturbances, skin diseases.
Season: May to October.
For information apply to: Hotel Association, Loèche-les-Bains, Switzerland.

PASSUGG.

Near Chur. Situated on a picturesque plateau. Mild sub-alpine climate. Vast forests.
Treatments: The Ulricus spring (alcaline-muriatic), Belvedra spring (chalybeate), Fortunatus spring (alcaline-muriatic with iodine), Helen spring (mildly alcaline and acid), Theopul spring. All varieties of accessory treatment. Dietetic treatment. Indications: Diseases of the digestive organs, diseases of the liver and bile ducts, kidney and bladder diseases, diseases of nutrition and metabolic diseases, especially diabetes, arterio-sclerosis, diseases of the blood and tropical diseases.
Season: May to October.
For information apply to: Spa Director, Passugg, Switzerland.

RHEINFELDEN.

10 miles from Basle, on the railway line Zürich-Basle. Famous for its vigorous brine, containing 31% salt, and for its "Kaiserquelle" spring, a highly diuretic calcium and boric acid well, and for its "Magdalena" spring, containing sulphates of calcium, sodium, and magnesium. 8 bath establishments with up-to-date installations. Treatments: brine baths, carbonic acid brine baths, drinking, mud-packs, "Mutterlauge" packs, inhalation, massage, gymnastics, all varieties of electric treatment, dietetic treatment. Recommended for: gout, rheumatism, arthritis, women's diseases, sterility, obesity, children's diseases, arterial hypertension, diseases of the heart, affections of muscles, bones, and joints, convalescence.
Any information and detailed booklet gladly supplied by: Enquiry Office, Rheinfelden, Switzerland.

SCHINZNACH.

Railway connections: Basle-Brugg-Zurich, and Berne-Brugg-Zürich. The hot springs of Schinznach were in use in Roman times and belong to the strongest radio-active sulphur wells on the Continent. Newly equipped, comfortable baths and inhalation rooms. Treatments: baths, drinking, sulphur-mud and sulphur-water packs, irrigations, inhalatorium, massage, X-rays. Recommended for: gout, rheumatism, affections of bones and joints, non-tuberculous catarrhs of the air passages, arterio-sclerosis, diseases of the skin, diseases of women, children's diseases.
Season: May to October.
For information apply to: Spa Director, Schinznach Bad, Switzerland.

TARASP-SCHULS-VULPERA.

The chief spa of the Lower Engadine. Glauber salts wells. The advantage of this spa lies in the combination of the curative properties of the waters with the alpine air and sun.
10 mineral springs of various composition. Up-to-date equipment for drinking and baths, air and sun baths, swimming baths, Zander-hall, X-ray institute, diet. Recommended for: affections of the digestive organs, metabolic ailments, nervous troubles, affections of the organs of circulation, of the organs of respiration, of the genito-urinary system, malaria.
Information supplied by: General Manager, Kurhaus Tarasp.

For information and the booklet "Swiss Spas and their Mineral Springs" (sent gratis), please apply to the Office of the Swiss Federal Railways, 11b, Regent Street, London, S.W.1.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel: Welbeck 8901.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) CH.M.EDINBURGH.
M.C.CANTAB.
F.R.C.S.EDINBURGH. M.S.LONDON.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S.," free on application to the Secretary.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

(UNIVERSITY OF LIVERPOOL.)

COURSES OF INSTRUCTION (lasting about three months) for the Diploma in Tropical Medicine commence on October 1st and January 6th, and for the Diploma in Tropical Hygiene on January 13th and April 23rd. (Candidates for the D.T.H. must possess the D.T.M. of this University.)

For particulars apply to the Hon. Dean, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool.

County Borough of Rochdale.

ASSISTANT MEDICAL OFFICER OF HEALTH AND CLINICAL TUBERCULOSIS OFFICER.

The Health Committee invite applications for the appointment of Assistant Medical Officer of Health and Clinical Tuberculosis Officer at salary of £700 per annum.

Candidates must be registered Medical Practitioners, and must be qualified to hold an appointment as Tuberculosis Officer and Venereal Diseases Officer, in accordance with the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, and must also possess the Diploma of Public Health.

The successful candidate will be required to devote the whole of his time to the duties of the office, which include attendance at the Tuberculosis and Venereal Diseases Clinics, also Bacteriological Laboratory work, or any other Public Health duties assigned by the Medical Officer of Health, under whose direction and supervision such officer will act.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, Rochdale, to whom all applications should be returned, endorsed "Assistant Medical Officer of Health," so as to be delivered not later than the first post on Tuesday, June 10th.

Town Hall, Rochdale. WM. HENRY HICKSON, Town Clerk.
May 19th, 1930.

WEST AFRICAN MEDICAL STAFF.

Vacancies at present exist for MEDICAL OFFICERS in the WEST AFRICAN MEDICAL STAFF.

Qualifications. Candidates must be British subjects of European parentage and under 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

Salary. £660 per annum, rising by annual increments of £30 per annum to £720 per annum, and then, on confirmation, £720 per annum, rising by annual increments of £40 to £960 per annum, together with a seniority allowance (payable only in West Africa) at the rate of £72 per annum. After three years' service on £960, the salary may be raised to the scale of £1,000 per annum, rising by annual increments of £50 to £1,150 per annum, together with a seniority allowance at the rate of £100 per annum.

Quarters. Free quarters are provided or an allowance is given in lieu.

Outfit Allowance. An outfit allowance of £60 is granted on first appointment.

Passages. Free first-class passages are provided for the officer only both on first appointment and when proceeding on or returning from leave. A married officer will, in certain circumstances, be granted half the cost of his wife's passages to and from West Africa.

Terms of Appointment. The appointments are pensionable, subject to a probationary period of three years in the first instance.

Tour of Service. The normal tour of service in West Africa is approximately 18 months, though vacation leave may be granted by the Governor after 12 months, and is followed by leave at the rate of one week for each completed month of residential service, plus the time necessarily spent in the voyages to and from England.

Course of Instruction in Tropical Medicine. Selected candidates will normally be required to attend a course of instruction in Tropical Medicine and Hygiene before proceeding overseas.

Duties. Though Medical Officers are appointed in the first instance for general service, there are good opportunities for work in special branches of medicine and surgery and for research.

Further particulars and forms of application may be obtained, on application in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Southern Rhodesia Medical SERVICE.

Three ASSISTANT AND RELIEVING GOVERNMENT MEDICAL OFFICERS are required for the Southern Rhodesia Medical Service. Salary £500 per annum, rising by £25 per annum to £650 per annum, with private practice.

Preference will be given to holders of Public Health or Tropical Medicine certificates.

Applications, with full particulars of qualifications, age, past appointments held, etc., with copies of references, should be addressed to the Official Secretary, Office of the High Commissioner for Southern Rhodesia, Crown House, Aldwych, London, W.C.2, from whom copies of conditions of appointment to the Southern Rhodesia Medical Service can be obtained.

City of Plymouth.

RESIDENT MEDICAL SUPERINTENDENT.

Applications are invited from duly qualified and registered Medical Practitioners for the post of Resident Medical Superintendent of the Plymouth City Hospital.

The salary will be at the rate of £1,000 per year, with food, quarters, lighting, heating, and washing. No canvassing for this appointment is permitted, and any canvassing will disqualify the applicant. The appointment will be terminable by three months' notice on either side.

Applicants must be holders of the F.R.C.S., or the Degree of a Master of Surgery in a University of the United Kingdom. The appointment is whole-time, and private practice is not permitted. The person appointed will be an Assistant Medical Officer in the Public Health Department, and will be on the staff of the Medical Officer of Health, who is the General Medical Superintendent of the Corporation Hospitals.

Applications will be considered only on the forms of application which will be provided. A form of application, together with further details relating to the appointment, can be obtained from the undersigned, on the receipt by him of a request for this, accompanied by a stamped and addressed envelope. Forms of application, duly completed, together with copies of not more than three recent testimonials, must be returned to the undersigned not later than June 5th.

Town Hall, Stonehouse, Plymouth. May 8th, 1930.
A. T. NANKIVELL, M.D., M.R.C.P., D.P.H., etc., Medical Officer of Health.

City of Plymouth.

DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Men for the post of whole-time Deputy Medical Officer of Health to the City of Plymouth.

Applicants must possess a Diploma in Public Health or a qualification in State Medicine.

The salary will be at the rate of £750 per annum, rising by annual increments of £50 to £900 per annum, and the appointment will be terminable by three months' notice on either side.

The person appointed will be required to act for the Medical Officer of Health in his absence, and generally to help him in the Public Health work of the City, and in the various Sub-departments of the Public Health Department. He will act under the general supervision and direction of the Medical Officer of Health, and carry out any duties delegated to him from time to time.

Forms of application will not be provided.

Candidates for this appointment should state their age and give an account of their professional qualifications and experience in all branches of Public Health work.

Canvassing will disqualify the applicant.

Applications must be received by the undersigned on or before Thursday, June 5th, and envelopes must be endorsed "Deputy Medical Officer of Health."

Town Hall, Stonehouse, Plymouth. May 8th, 1930.
A. T. NANKIVELL, M.D., M.R.C.P., D.P.H., Medical Officer of Health, City and Port of Plymouth.

GERALD A. KENYON, Asst. Secretary.

City and County of Kingston-upon-Hull.

APPOINTMENT OF TUBERCULOSIS OFFICER.

The Corporation invite applications for the post of Clinical Tuberculosis Officer at a commencing salary of £800, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £1,000 per annum. The age of candidates is not to exceed 40 years.

Candidates should either have held a previous appointment as Tuberculosis Officer with the approval of the Ministry of Health, or should, subsequent to qualification—

(1) Have had at least three years' experience in the practice of their profession;

(2) Have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by General Medical or Surgical cases; and

(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis.

The gentleman appointed will rank as a Senior Assistant Medical Officer of Health, and will work under the general administrative control of the Medical Officer of Health.

As the post is a designated post under the Local Government and Other Officers Superannuation Act, 1922, the successful candidate will be required to undergo a medical examination.

Forms of application, which are obtainable from the undersigned, should be returned so as to be received not later than June 14th.

N.B.—This advertisement is again being issued owing to the withdrawal of the candidate appointed in April on account of his accepting subsequently another post.

W. M. FRAZER,
Medical Officer of Health.

Health Dept.,
Guildhall,
Hull. May, 1930.

City and County of Bristol.

CHIEF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT PORT MEDICAL OFFICER.

The Corporation of Bristol invite applications for the post of Chief Assistant Medical Officer of Health and Assistant Port Medical Officer.

The gentleman appointed must possess the Diploma in Public Health or a similar qualification in State Medicine. He will be required to devote the whole of his time to his duties and will not be allowed to engage in private practice. He will work under the direction of the Medical Officer of Health in the City Health Department and in the Port, and also in the Inspection of Aliens if appointed to do so by the Ministry of Health. The appointment will be subject to one month's notice on either side and to the provisions of the Local Government and Other Officers Superannuation Act, 1922, for which purpose the candidate will be required to pass a medical examination.

Salary will be £800, rising to £1,000 per annum by annual increments of £100.

Applications must be made on a prescribed form, which may be obtained from the undersigned, and must be delivered at the Council House, Bristol, not later than Friday, June 13th. Envelopes should be endorsed "Assistant M.O.H."

Canvassing of Members of the Council, either directly or indirectly, will disqualify.

JOSIAH GREEN,
Town Clerk.

The Council House,
Bristol.
May 25th, 1930.

Royal Northern Hospital,

Holloway, London, N.

Applications are invited for the post of HOUSE SURGEON. The appointment is for nine months (six months as House Surgeon and three months as Casualty Officer) from July 15th. Salary at the rate of £70 per annum, with board, residence, and laundry.

Applications, with copies of testimonials, should be sent by June 7th to the undersigned, from whom forms of application and rules can be obtained.

GILBERT G. PANTER,
Secretary.

The Willesden General Hospital

(Incorporated), N.W.10.
(106 Beds.)

APPOINTMENT OF HOUSE PHYSICIAN.

Applications are invited for the above appointment. Candidates must be duly registered under the Medical Acts, and unmarried.

Salary at the rate of £100 per annum.

Detailed applications, with copies of testimonials, to be sent as soon as possible to the undersigned

R. J. HEARNE,
Secretary.

April 19th, 1930.

Kent Education Committee.

SCHOOL MEDICAL SERVICE.

SCHOOL MEDICAL INSPECTOR (Woman).

The Kent Education Committee invite applications for the appointment of a permanent School Medical Inspector, to act under the supervision of the School Medical Officer. The duties will consist mainly of work in connection with secondary and private schools, together with some elementary school work and such other duties as may be allotted to the officer. The appointment is open to women doctors only.

The selected candidate will be required to devote the whole of her time to the duties of the office.

The salary offered is at the rate of £600 per annum, rising by £12 10s. increments to £650 per annum, together with travelling and subsistence allowances.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and will be terminable by three months' notice on either side. The successful candidate will be required to pass a medical examination as to physical fitness.

Applications, stating age and full qualifications, and accompanied by copies of three recent testimonials, must be forwarded to the undersigned not later than June 14th.

No official form of application will be issued, and canvassing will be considered a disqualification.

ALFRED GREENWOOD, M.D.,
School Medical Officer.

Sessions House,
Maidstone.
May 5th, 1930.

Borough of St. Marylebone.

ASSISTANT MEDICAL OFFICER AND PUBLIC VACCINATOR (Male).

Applications are invited from duly qualified and registered Medical Practitioners for the position of a Whole-time Assistant Medical Officer of Health and Public Vaccinator (male). APPOINTMENTS.—Contd.

Lindsey County Council and SCUNTHORPE AND FRODINGHAM URBAN DISTRICT COUNCIL.

MEDICAL OFFICER OF HEALTH AND ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited from duly qualified and registered male Medical Practitioners, holding the Diploma in Public Health or its equivalent, for the above-mentioned whole-time joint appointment. Candidates must not exceed 40 years of age. The joint salary covering both appointments will be at the rate of £800 per annum, with £100 per annum for the maintenance of a motor car to be provided by the officer.

As regards the Urban District Council, the appointment will be held in accordance with the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926, and, as regards the County Council, the appointment will be made in accordance with the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930.

The officer will be required to carry out such duties as may from time to time be required of him as Assistant County Medical Officer. Such duties will be discharged under the general supervision of the Medical Officer of Health for the County and may include (inter alia) the following:

(a) School Medical Inspection.
(b) Treatment of Tuberculosis.
(c) Treatment of Venereal Diseases.
(d) Certification of Mental Defectives.
(e) Medical Superintendent of Brumby Isolation Hospital (Infectious Disease and Tuberculosis.

Applications, endorsed "Medical Officer," on the prescribed form, together with copies of not more than three recent testimonials, must be received by the Clerk of the Urban District Council, Council Offices, Scunthorpe, not later than June 10th.

Canvassing in any form will be a disqualification.

J. F. AULD,
Clerk to the Urban District Council,
Scunthorpe.
ERIC W. SCORER,
Clerk of the County Council, Lincoln.
May 27th, 1930.

General Infirmary, Salisbury.
(General Hospital—151 Beds.)

Two HOUSE SURGEONS (male) required to commence duty at the end of June and the beginning of July.

Candidates must be unmarried, fully qualified, and registered. Salary £150, with board, etc.

Applications, with copies of testimonials, to be sent to the House Governor and Secretary, from whom a copy of the rules may be obtained on application.

The Weir Hospital,
Grove Road, Balham, S.W.12.

JUNIOR RESIDENT MEDICAL OFFICER (male, unmarried) required. Candidates must be fully qualified and duly registered. Salary £150 per annum, with board, residence, and laundry. Application, with copies of testimonials, to be sent to the Secretary, from whom further information may be obtained.

North Riding Mental Hospital, YORK.

LOCUM TENENS MEDICAL OFFICER required for July and August. Salary £7 7s. a week.

Applications, stating age and full particulars of qualifications and experience, and enclosing recent testimonials, to be addressed the Medical Superintendent.

Bucks County Council,
BUCKINGHAM BOROUGH COUNCIL,
BLETCHLEY URBAN DISTRICT COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER AND MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified Medical Men with experience in Public Health duties, holding a Diploma of Public Health, for the following joint appointment:

(a) MEDICAL OFFICER OF HEALTH for the Borough of Buckingham and the Urban District of Bletchley.
(b) ASSISTANT COUNTY MEDICAL OFFICER to act as School Medical Inspector and Infant Welfare Officer for the following districts: Buckingham Borough, the Urban Districts of Bletchley, Linslade, Wolverton and Newport Pagnell, and the Rural Districts of Buckingham, Winslow, Wing and Newport Pagnell.

Salary £700 per annum, rising, subject to satisfactory service, by annual increments of £25 to £800 per annum.

Travelling expenses will be paid on the County Council scale, but a portion of the salary will be subject to superannuation deduction at 5 per cent.

Applicants should not be over 45 years of age, and will be required to pass a medical examination as to physical fitness, and the final appointment will be subject thereto.

The appointment is subject to the approval of the Ministry of Health and to the particulars and conditions of appointment set out on the form of application, which can be obtained from the Clerk of the County Council, County Hall, Aylesbury.

Office accommodation and the necessary clerical assistance will be provided.

Applications on the prescribed form, accompanied by copies of not more than three recent testimonials, which will not be returned, should be addressed to the Clerk of the Bucks County Council, and delivered at the County Hall, Aylesbury, not later than 10 a.m. on Monday, June 16th, marked "Medical Officer."

GUY R. CROUCH,
Clerk of the County Council.
PHILIP WOOD,
Town Clerk, Buckingham.
F. E. CAPPER,
Clerk of the Bletchley Urban District Council.
County Hall, Aylesbury. May 26th, 1930.

St. Peter's Hospital for Stone, ETC.,
Henrietta Street, Covent Garden, W.C.2.

CLINICAL ASSISTANTS are required by the following members of the Honorary Staff, who attend the Out-patient Department as indicated:

Mr. Swift Joly	Mondays 2 to 5 p.m.
Mr. Clifford Morson	Saturdays 2 to 7 p.m.
Mr. Barrington	Tuesdays 2 to 5 p.m. Thursdays 3 to 7 p.m.
Mr. Ogier Ward	Wednesdays 3 to 6 p.m. Fridays 2 to 5 p.m. (Women and Children)
Mr. Alban Andrews	Mondays 5 to 7 p.m. Fridays 5 to 7 p.m

Appointments are made for six months from July 1st, 1930, a fee of five guineas being payable to the Hospital.

Applications will be received by the undersigned up to the first post on Wednesday, June 11th, 1930.

BEECHEY ROGERS, Secretary.

Hospital for Women at Leeds.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,

Tele. Address: Triform, Wesdo—London.

Oxford Street, W.1.

Telephone: Mayfair {1782 1789

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

1. WEST OF ENGLAND.—(Within 100 miles of London).—PLEASANT TOWN.—*Old-established* mixed general PRACTICE. Average income for last 2 years about £1,250, including panel of 1,200. Fees 2/6 to 6/-, and a few at 10/6. Little midwifery. Excellent house, recently redecorated, with ample accommodation. Garden. Garage. *Good* sport and schools. Premium for Practice and house £4,500.
2. NORTH LONDON.—Old-established good middle class PRACTICE, held by Vendor 25 years. Gross cash receipts for immediate past twelve months £2,811. Selected panel of about 250. Fees from 5/- upwards. Mids. from 7 gns. (only few cases). Very good corner house, non-basement, with 3 *reception*, 5 bedrooms, etc. Price for leasehold £1,600. Premium only £3,000.
3. LONDON, S.W.—Within easy reach of Charing Cross.—Good middle-class non-panel PRACTICE, averaging over £2,000 p.a. Fees 2/6 to 10/6. Mids. 3 to 10 gns. (about 12 cases). Suitable house, with 2 reception, 5 bedrooms, etc. Garden. Rent on lease £65 p.a. Premium £3,000.
4. SOUTH-WEST OF SCOTLAND.—COAST TOWN.—Old-established, non-dispensing, good mixed PRACTICE. Income for the last year £1,100, including panel of 400 and increasing. Fees 2/6 to 2 gns. Good house, with 2 reception, 5 bedrooms, etc., rent on lease £42 p.a., or could be bought for £1,300. Premium £1,000.
5. BIRMINGHAM SUBURB. — Well-established and rapidly increasing mainly working-class PRACTICE, producing for last year £765. Panel of 860. Visits 2/6 to 7/6, practically all cash. Little midwifery. Suitable small house (on lease 77 years). Price £600. Premium £1,050.
6. SOUTH DEVON.—COUNTRY PRACTICE, steadily increasing, and situated in very pleasant agricultural district, within easy reach of coast. Gross cash receipts for past 12 months £2,326. Panel produces, with mileage, about £420. Fees 5/6 to 21/-. Only about 20 cases of midwifery from 2 to 5 gns. Suitable house, in main street, with 2 reception, 5 bedrooms, etc. Garden. Garage. Rent on lease £50 p.a. Good sport. Premium £2,800.
7. SOMERSET.—Attractive Town, within easy reach of coast.—Old-established and increasing PRACTICE, producing for the immediate past twelve months over £3,000, including panel of 1880, and appts. worth about £250. Fees 2/6 to 21/-. Cottage Hospital, and good surgical scope. Two very suitable houses available at very moderate rents. Sport of all kinds. Premium £4,500.
8. SOUTH OF ENGLAND (Thriving Seaport Town, pop. over 30,000).—Old-established mixed-class PRACTICE, averaging at present £500 p.a., but offering exceptional *scope*. Panel of about 430 and 2 small appts. Visits 5/6 to 5/-. Practically no midwifery. Very attractive residence, on main road and near the sea, with professional rooms, 2 reception, 4 bedrooms, bathroom, etc. Pretty garden. Garage. Rent on lease £100 p.a. Premium 1½ years' purchase.
9. WITHIN TEN MILES OF GLASGOW. — Prosperous old-established good middle and better-class PRACTICE, producing an average of nearly £2,950 p.a., including panel of 2,300 and appts worth £500. Fees 2/6 to 21/-, medicine extra. Mid. from 2 gns. upwards. Very good detached house, with 3 reception, 5 bedrooms, etc. Garden. Garage. Can be purchased, or other residence secured. Premium 1½ years' purchase, £1,500 down, and balance as arranged.
10. PARTNERSHIP.—MIDLANDS.—COUNTY TOWN.—TWO ONE-FIFTH SHARES (suitable two friends or will be sold separately) are offered in a very old-established good mixed Practice owing to the retirement of the senior of two partners. Gross cash receipts for immediate past 12 months over £5,900, including panel of 3,400. Fees from 4/-. Not much midwifery. Good house, with 2 reception, 6 bedrooms, etc. Rent on lease £75 p.a. Premium for share two years' purchase.
11. SOMERSET COAST.—*In a small but increasing and delightful seaside resort*, the five-twelfths share of a very old-established PRACTICE, producing last financial year £1,600, but offering exceptional scope. Panel brings in £480 and appointments. Visits 5/- to 4 guineas. Mid. 4 to 6 gns.; only about 12 cases yearly. Choice of 2 suitable houses (price, freehold, £950), with gardens. Electric light and gas. Premium 2 years' purchase.
12. SOUTH-WEST COAST.—*VERY FAVOURITE RESORT.—Old-established* good middle-class non-panel PRACTICE, held by Vendor (who is retiring) over 20 years. Receipts average £1,142. Fees 5/- to 10/6 and upwards. Mids. 5 to 15 gns. (about 12 cases). House is an exceptionally good one, in perfect order, with ample accommodation, central heating, electric light. Good garden. Garage. Price for freehold £3,250. Premium 1½ years' purchase.
13. CORNISH RIVIERA.—Old-established good mixed PRACTICE in exceptionally attractive village which is steadily increasing. Receipts for last 12 months £1,300, including panel of over 400. Visits 5/- to 21/-. Excellent house, facing due south, with 6 bedrooms, etc. Good garden. Rent on lease £56 p.a. Premium £1,800.
14. YORKS (NORTH RIDING).—In a small pleasant market town, with pretty and prosperous surrounding country, very old-established mixed-class PRACTICE averaging £1,247 p.a., including appts. worth £80 and panel producing last year £356. Visits 3/6 to 25/-. One opponent. Good house, facing south (3 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Electric light. Vendor's freehold. Price £1,550 (£1,000 on mortgage), or would let for few years at £80 p.a. Premium £1,500. Educational and social amenities.
15. SOUTH YORKS.—GOOD TOWN. — Old-established *good* middle-class PRACTICE, producing for last twelve months nearly £4,500. Small selected panel of 400. Fees 5/- to 10/-. Mid. 2 to 10 gns. (only about 50 cases yearly). Suitable house, with 3 reception, 6 bedrooms, etc., and professional rooms. Electric light. *Good* garden. Garage for 3 cars. Rent on lease £160 p.a. Excellent schools, sport, etc. Premium £5,700.
16. KENT.—Pleasant Seaside and residential Town (pop. 17,000).—Old-estab. non-dispensing middle and working-class PRACTICE, averaging for the past 3 years over £1,650 p.a. including transferable appt. worth about £200 and panel of 500. Visits 3/6 to 10/6. House contains 8 rooms, kitchen, bathroom, etc. Garden. Garage. Price *freehold* £1,500, but might be rented. Premium £1,500.
17. LINCS.—Very old-estab. easily worked Village PRACTICE, averaging £1,335 p.a., including panel and appts., producing £740 p.a. Fees from 2/6. Not much midwifery. Nearest opponent 6 miles. Suitable house, with 3 reception, 4—5 bedrooms, bathroom, etc. One acre of garden. Price £900. Good sport and schools within reach. Premium 1½ years' purchase. Cottage Hospital.
18. MANCHESTER.—PRACTICE is situated in a growing district offering very large scope. Income about £1,700 p.a., including panel producing £430. Fees 3/6 upwards. Excellent detached house, well situated, with 3 reception, 5 bedrooms, etc., all in good order. Price £1,600. Premium 1½ years' purchase.
19. HANTS.—COUNTRY PRACTICE.—Very old-established, situated in most attractive district near Sussex Border. Receipts average over £800 p.a. Panel of 480. Detached house in half an acre of garden, 2 reception, 5 bedrooms, etc. Rent £55 p.a. Hunting, golf, etc., and first-class schools within reach. Premium £1,500.
20. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large *scope* for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
21. YORKS.—In a clean and thriving manufacturing town, an *old-established* Homœopathic and partly Allopathic PRACTICE, held about 50 years by Vendor who is retiring. Cash receipts for the past three years average £2,400 p.a. Patients middle and better-class. Midwifery refused. Good house available, rent £100 p.a. Premium only one year's purchase, part down and balance by arrangement.
22. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
23. CHESHIRE.—Industrial Town within easy reach of Manchester.—Well-established PRACTICE *producing £2,600* p.a., with panel of 2,870. *Fees 2/6 to 3/6, medicine extra. Good house, with ample* accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
24. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—Old-established mixed general PRACTICE. Average income nearly £1,900. Panel of 2,500. Fees 2/6 to 7/-. No mids. No Assistant kept. Well-situated house, with good accommodation. Rent on lease £120. Prem. £3,300.
25. WITHIN 40 MILES OF LONDON.—In a thriving Riverside and Hospital town (pop. over 40,000).—Old-established mixed-class and increasing PRACTICE worth over £2,300 last year, including panel of 1,600 to 1,700. House contains professional accommodation, 2 reception, 4 bedrooms, bathroom, etc. Small garden and garage. Rent on lease £60 p.a. *Premium* £3,650, to include good book debts of £500, drugs, etc., and consulting room and surgery furniture.
26. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). Very little midwifery. One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Water laid on and gas plant installed. Rent £50 p.a. Premium £1,400. Excellent sport.
27. PARTNERSHIP.—WEST MIDLANDS.—The Third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional beauty. Cash receipts average £2 367 p.a., including panel of 1,624. Opposition not strong. Expenses light. Choice of two houses (small) which can be bought for £500 or £700. Premium 2 years' purchase.
28. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1¼ acres. Price, freehold, £3,500. Premium 1½ years' purchase.
29. WITHIN FIFTY MILES OF LONDON.—In a pretty residential district, a well-established PRACTICE averaging over £700 p.a., including panel of 338, and appts. worth about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Elec. light. Price for freehold £3,000. Premium £1,050. Exceptionally good educational facilities for boys.

Full Schedule of Terms and Conditions will be forwarded on application.

Valentine's Meat-Juice

In Typhoid Fever, Diarrhoea and Cholera Infantum, when it is **Essential** to **Sustain** the patient **without irritating** the **Digestive Organs,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

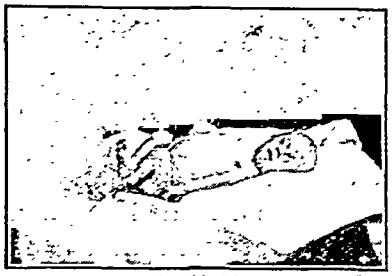
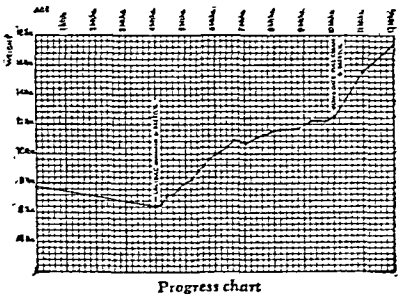
NATURALLY RICH

IN VITAMIN "D"



A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs 9 ozs.) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia. The infant was put on to *LACIDAC* (Separated) with a small quantity of *BRESTOL* and immediately made steady progress.



At 6 months he had gained 3 lbs. 7 ozs. and by the end of another 4 months his weight was 12 lbs. 6 ozs., and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol.

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby.

His Doctor considers him a '*Resurrection.*'

AMENORRHEA
DYSMENORRHEA

"It is a very great mistake to treat amenorrhea as though it were simply a lack of the catamenia, for it is a great deal more than that. Behind this lack lies a cause. It may be in the uterus or the ovaries, or it may be still farther back in the secretions of the endocrine glands or in the functioning of the vegetative nervous system."—("The Treatment of Amenorrhea," Dalché, *Revue Française de Gynecologie et d'Obstetrique*, May 1, 1920.)

In the treatment of irregularities of the catamenia, rational therapeutic procedure is directed to the restoration of normal balance in the endocrine and vegetative nervous systems.

Hormotone
BRAND

contains thyroid, pituitary, adrenal, and gonad substance, combined to take advantage of the demonstrated synergism existing between them. In the treatment of these disorders Hormotone has been very successful.

Dose: One or two tablets three times daily.

No. 3622. SATURDAY, JUNE 7, 1930. Price 1/3

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital is now open for suitable general surgical cases at 17, Park Lane, London, W.1. The fees for a room cost now only two guineas a week, interest in the project having made possible a series of four reductions since the scheme was started.

(The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses, and yet at the same time to avoid any semblance of a charity which would be distasteful to such.)

(The only condition attaching to the endowment is that any advantages—such as they are—should be widely advertised and not in any way limited to any small section of the community. A further promise is made that if, and as, more beds are required they will be provided.)

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane.
Telephones: Grosvenor 2312 & 2313.

A Typical Scale of Reduced Fees for Surgical Cases in the Annexe Clinic of the Harold Fink Memorial Hospital at 17, Park Lane.

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	£6 6 0
Dressings, Theatre Fees, etc.	1 1 0
Anæsthetic Fee	3 3 0
Surgical Fees for Major Operation (nominal fee only according to patient's means) (say, from)	10 10 0
(From Twenty guineas inclusive fee)	£21 0 0

The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant, who may of course be present at the operation, and who, if convenient to himself, will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance.

When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in-Chief (with a view, for example, to a Bismuth Meal, Cystoscopic, X-ray Examination, etc.), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made. (Proportionately reduced nominal fees only charged therefor.)

Telephones: Grosvenor 2312 & 2313.

All rooms are of course separate, and hold one patient only, there being no wards.

SANDOZ

FELAMINE BRAND SANDOZ

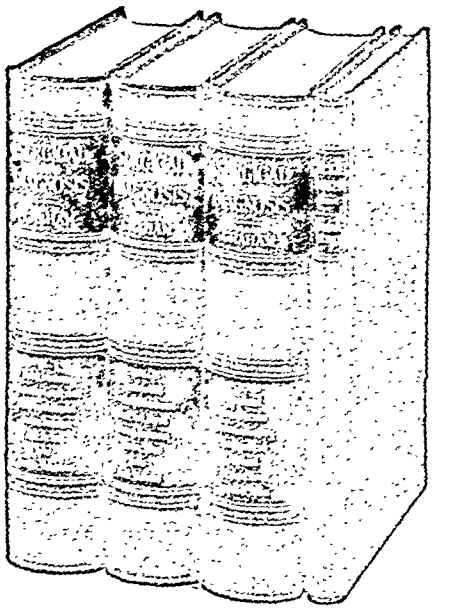
AIMED TO MAKE YOUR DIAGNOSES LESS PRESUMPTIVE



NEW

Graham's Surgical Diagnosis

NEW not alone in publication date—it is just ready—but new and fresh and modern in its content, in the practical everyday help it offers the Medical Profession. It is the finest work on the subject for many years.

GRAHAM'S Surgical Diagnosis is diagnosis in detail. It is the thorough presentation of every aspect—history-taking, examination of the patient, symptoms, complications, atypical as well as typical cases—all making for completeness and accuracy.

By a painstaking discussion of differential diagnosis, misleading signs and symptoms are explained and the many clinical presentations of a disease or condition are set out in sharp outline. Indeed, this clinical tone is immediately perceived upon opening the work and springs from the practical experience of the authors.

Bedside and laboratory methods are described, the guiding idea throughout being to help you make your diagnoses more accurate, less presumptive. But Dr. Graham does not stop here; he includes full consideration of the diagnosis of post-operative complications—those dangerous sequelae which are frequently dismissed briefly. There are 1,275 illustrations.

"THE LANCET," reviewing Volumes 1 & 2, says:

"The list of distinguished surgeons who contribute to the work prepares the reader for a surgical feast, and his expectations are realised. . . . These volumes are in themselves a fine achievement, and will make all those who come across them eager to possess the completed work."

Three octavo volumes totalling 2,750 pages, with 1,275 illustrations and a separate Desk Index Volume. By 43 American authors. Edited by EVARTS A. GRAHAM, M.D., Bixby Professor of Surgery, Washington University, St. Louis. Per set: Cloth, £7 10s. net.

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street LONDON, W.C.2

H. K. LEWIS & CO. LTD.

RECENTLY PUBLISHED. With 111 Illustrations. Demy 8vo. 15s. net, postage 9d.

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4.

THE PRACTITIONER

THE LEADING MONTHLY MEDICAL JOURNAL.

FOUNDED IN THE YEAR 1868.

CONTROLLING EDITOR: SIR HUMPHRY D. ROLLESTON, BART., G.C.V.O., K.C.B., M.D., F.R.C.P.
ASSOCIATE EDITOR: R. SCOTT STEVENSON, M.D., F.R.C.S.E.

The most urgent problems of everyday medical practice are those connected with children's ailments. It is therefore the duty of every medical practitioner to keep in touch with the most recent advances in the diagnosis and treatment of DISEASES OF CHILDREN. The leading British authorities on pædiatrics are contributing to the July Special Number of THE PRACTITIONER, which contains 250 pages of text and numerous illustrations.

Among the contributors are the following:—

SIR ROBERT JONES, Bart., K.B.E., C.B., Ch.M., F.R.C.S.
Lecturer on Orthopædic Surgery, Liverpool University.

ROBERT HUTCHISON, M.D., F.R.C.P.
Physician, London Hospital and Hospital for Sick Children, Great Ormond Street.

LEONARD HILL, M.B., F.R.S.
Director, Department of Applied Physiology, National Institute for Medical Research.

ERIC PRITCHARD, M.A., M.D., F.R.C.P.
Medical Director of the Infants' Hospital.

R. C. ELMSLIE, M.S., F.R.C.S.
Orthopædic Surgeon, St. Bartholomew's Hospital.

F. J. POYNTON, M.D., F.R.C.P.
Physician, University College Hospital and Hospital for Sick Children, Great Ormond Street.

P. G. DOYNE, B.M., F.R.C.S.
Ophthalmic Surgeon, Hospital for Sick Children, Great Ormond Street.

G. F. STILL, M.A., M.D., F.R.C.P.
Physician for Diseases of Children, King's College Hospital.

H. MORLEY FLETCHER, M.A., M.D., F.R.C.P.
President of the Pædiatric Association of Great Britain; Consulting Physician, St Bartholomew's Hospital.

JOHN FRASER, M.C., M.D., Ch.M., F.R.C.S.E.
Regius Professor of Clinical Surgery, University of Edinburgh.

R. C. JEWESBURY, M.A., M.D., F.R.C.P.
Physician-in-charge, Children's Department, St. Thomas's Hospital.

L. G. PARSONS, M.D., F.R.C.P.
Professor of Diseases of Children, Birmingham.

REGINALD MILLER, M.D., F.R.C.P.
Physician, Paddington Green Children's Hospital.

W. G. WYLLIE, M.D., M.R.C.P.
Physician to Out-Patients, Hospital for Sick Children, Great Ormond Street

LEONARD FINDLAY, D.Sc., M.D., F.R.F.P.S.
Professor of Pædiatrics, Glasgow University.

CHARLES McNEIL, M.A., M.D., F.R.C.P.E.
Physician, Royal Edinburgh Hospital for Sick Children.

DONALD PATERSON, M.D., F.R.C.P.
Physician for Diseases of Children, Westminster Hospital.

J. D. ROLLESTON, M.A., M.D., M.R.C.P.
Medical Superintendent, Western Hospital, London County Council.

C. F. HARRIS, M.D., M.R.C.P.
Physician, Children's Department, St. Bartholomew's Hospital.

H. GARDINER-HILL, M.B.E., M.A., M.D., F.R.C.P.
Research Assistant, Medical Unit, St. Thomas's Hospital.

W. J. O'DONOVAN, O.B.E., M.D., M.R.C.P.
Physician for Skin Diseases, London Hospital.

Order Form.

THE HARLEY STREET CALENDAR
By H. H. BASHFORD, M.D.
7s. 6d. net.
Punch.—"Eleven studies of English-speaking medical men. A book whose large outlook and delicate style are a continual joy."

THE CORNER OF HARLEY STREET
By H. H. BASHFORD, M.D.
CONSTABLE'S MISCELLANY.
3s. 6d. net.
Lancet.—"The book is pervaded with a humour, whimsical rather than mordant, which should help the reader to face alike the tragedy and the pathos of life."

HEREDITY IN MAN
By R. RUGGLES GATES, Ph.D., F.L.S.
British Medical Journal.—"... it is an important contribution to scientific literature."
Health and Empire.—"Prof. Gates is to be congratulated on giving to the public a book so well stocked with reliable information."
Times Literary Supplement.—"A useful contribution to a fascinating and important subject."
Illustrated, 24s. net.

CONSTABLE

MARRIAGE, PAST, PRESENT & FUTURE
By RALPH DE POMERAI.
15s. net.
The history and development of the practice of marriage and divorce throughout the world from the time of the primitive man down to the present, and the probable tendencies of the future.

THE TASK OF SOCIAL HYGIENE
By HAVELOCK ELLIS.
New Edition. 6s. net.
Saturday Review.—"The book reveals a profundity of learning and a breadth of vision which will leave very few of its readers uninformed or uninspired."

BEING WELL BORN. *An Introduction to Heredity and Eugenics.*
By MICHAEL F. GUYER.
2nd Edition. 21s. net.
Spectator.—"'Being Well Born' is a standard book. Now brought up to date it can be recommended to anyone wishing to get a sound grasp of the biological basis of eugenics."

THE ANGLO-FRENCH LIBRARY OF MEDICAL AND BIOLOGICAL SCIENCE

Edited by

F. G. CROOKSHANK, M.D., F.R.C.P. (London) *and* RENÉ CRUCHET (Professor in the University of Bordeaux)

FIRST SIX VOLUMES.

DIATHERMY IN OTO-LARYNGOLOGY

By DAN MACKENZIE, M.D., F.R.C.S.E., Consulting Surgeon, Central London Throat and Ear Hospital. 10s. 6d. net.

A complete account of the applications of Diathermy in Modern Oto-Laryngological Practice. The author, whose own work has so advanced the utility of the method, discusses the subject from the theoretical, clinical, and technical standpoints.

THE MYCOSES OF THE SPLEEN

By ALEXANDER GEORGE GIBSON, M.D., F.R.C.P., Physician to the Radcliffe Infirmary, and Reader in Morbid Anatomy, University of Oxford. 12s. 6d. net.

Professor Nanta and others demonstrated the presence of mycelial structures in the spleens of persons suffering from Banti's disease. The author has also identified such structures, and here gives an account of his own work as well as of recent Continental researches

THE OEDEMA OF BRIGHT'S DISEASE

By CH. ACHARD, Professor in the Faculty of Medicine of Paris. 9s. net.

A detailed study of the pathological, biochemical, and clinical features of oedema, with an exhaustive study of its pathogenesis showing that the oedema of Bright's disease is mainly due, like oedema in general, to disturbance of an extra renal function.

DISEASE AND THE MAN

By GEORGE DRAPER, M.D. With 43 Illustrations, 12s. 6d. net.

"He urges the physician to study, not only disease but man, that he may be able to view the patient's personality from every angle. The present work sums up his conclusions respecting co-relations between morphological, physiological, immunological, and psychological characters. A well-arranged text, supplemented by admirable illustrations, makes the work pleasant to read."
—*Times Literary Supplement.*

EPIDEMIOLOGY OLD AND NEW

By Sir WM. HAMER, M.D., F.R.C.P. 9s. net.

"An important contribution to the study of epidemiology. Should be read by all who practise the science and art of medicine."—*Medical Officer.*

ASPECTS OF AGE, LIFE, AND DISEASE

By Sir HUMPHRY ROLLESTON, Bt., M.D., LL.D. 10s. 6d. net.

"Betrays a capacity to make out of varied details a pleasing, instructive, and inspiring story. The universal attitude will be one of congratulation."—*British Medical Journal*

PHYSIQUE AND CHARACTER

By E. KRETSCHMER. 31 Plates, 15s. net.

His contributions to psychiatry are practically unknown in this country, and we therefore welcome a translation of his notable work. Such researches must be considered of fundamental importance."—*British Medical Journal*

BIRTH CONTROL, ABORTION, AND STERILIZATION

JOHN BALE, SONS & DANIELSSON, Ltd.

THE PRINCIPLES OF ANTE-NATAL AND POST-NATAL CHILD HYGIENE. By W. M. FELDMAN, M.D., B.S., M.R.C.P.Lond., F.R.S.Edin. With 161 Illustrations and 14 Plates, including over 100 Portraits. **25s.** net; post free 25s. 9d.

"The author has attempted, and has succeeded in, the difficult task of producing a book which will interest alike pædiatric physicians, lay workers at infant welfare centres, students of ante-natal care and welfare, and all concerned with the well-being of children. The general practitioner will find in it answers to the innumerable questions of young parents. . . These and other subjects are dealt with concisely but in detail, the attractive style of the writing preventing the weariness in reading that would otherwise be inevitable."—BRITISH MEDICAL JOURNAL.

DISEASES OF THE NEWBORN. By Dr. AUGUST RITTER VON REUSS. Translation revised by John D. Rolleston, M.D., B.Ch., M.A., Editor of the "British Journal of Children's Diseases." With 90 Illustrations. **52s. 6d.** net; post free 53s. 9d.

"Of great importance . . . deals more thoroughly with the subject of the newborn than any we can call to mind."—LANCET.

A HANDBOOK FOR MOTHERS. By C. PHYLLIS ARMITAGE. Foreword by Gerald Quin Lennane, M.C. **2s. 6d.** net, post free.

A BOOK THAT DOCTORS CAN CONFIDENTLY RECOMMEND TO MOTHERS.

The only book that contains advice to mothers from the beginning of pregnancy to after school age, and in a far more compact form than any other book of its kind.

"We have no hesitation in recommending the little manual as a reliable book of reference."—NURSING MIRROR AND MIDWIVES JOUR.

THE CHILD OF CIRCUMSTANCE—THE MYSTERY OF THE UNBORN. By ALBERT WILSON, M.D.Edin. With Forewords by the Rev. R. J. Campbell, D.D., and Joseph Shaw Bolton, M.D., F.R.C.P., D.Sc., and Memoir of the Author. 67 Illus., including a Portrait of the Author. **15s.** net; post free 15s. 9d.

"To describe the book as interesting without the addition of a superlative would not do the author justice. It is *most* interesting—alike in the experiences of the author derived from direct association with and study of criminals of various types and in the conclusions derived therefrom . . . ***this very interesting treatise that lawyer, physician, and social reformer alike may study with interest and profit.***"—THE LAW JOURNAL.

83-91, GREAT TITCHFIELD STREET, LONDON, W.1.

New Pocket MAY DIAGNOSTIC SET

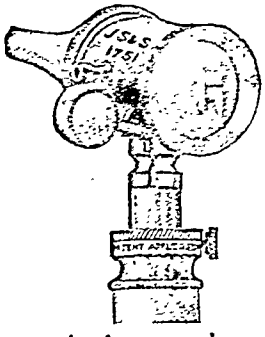
British Made

For EYE, EAR & THROAT.

MAY ELECTRIC OPHTHALMOSCOPE and ELECTRIC AURISCOPE

Fitted with two Speculae of different apertures, and nozzle for inflation of the Ear Drum.

TONGUE SPATULA



For throat examination—fits in place of the Speculum. Complete with spare Lamp and spare Battery in Velvet-Lined Case.

Price, 84/-

All parts are interchangeable with same battery handle. Fitted with Flash and Continuous Light Switch.

Patent applied for.

AURISCOPE

For Diagnostic Work the Lenses focus beyond the tip of the Speculum, so that when the patient is being examined the membrana tympani is correctly in focus.

For Operative Work the new Lock-on Switch can be fixed to give continuous light.

The Side Lens is fitted on the left-hand side—this gives a larger area for operating. The nozzle for inflation of the Ear Drum is also fitted on the left-hand side.

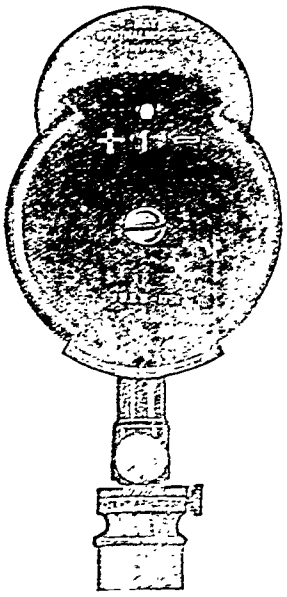
Auriscope only **Price, 32/6**

In Velvet-Lined Case with spare Battery - - 37/6

LUCAE'S MYRINGOTOME, for Paracentesis operation through the Auriscope. 5/-

SMALL SPECULUM for Children. 2/9

OPHTHALMOSCOPE



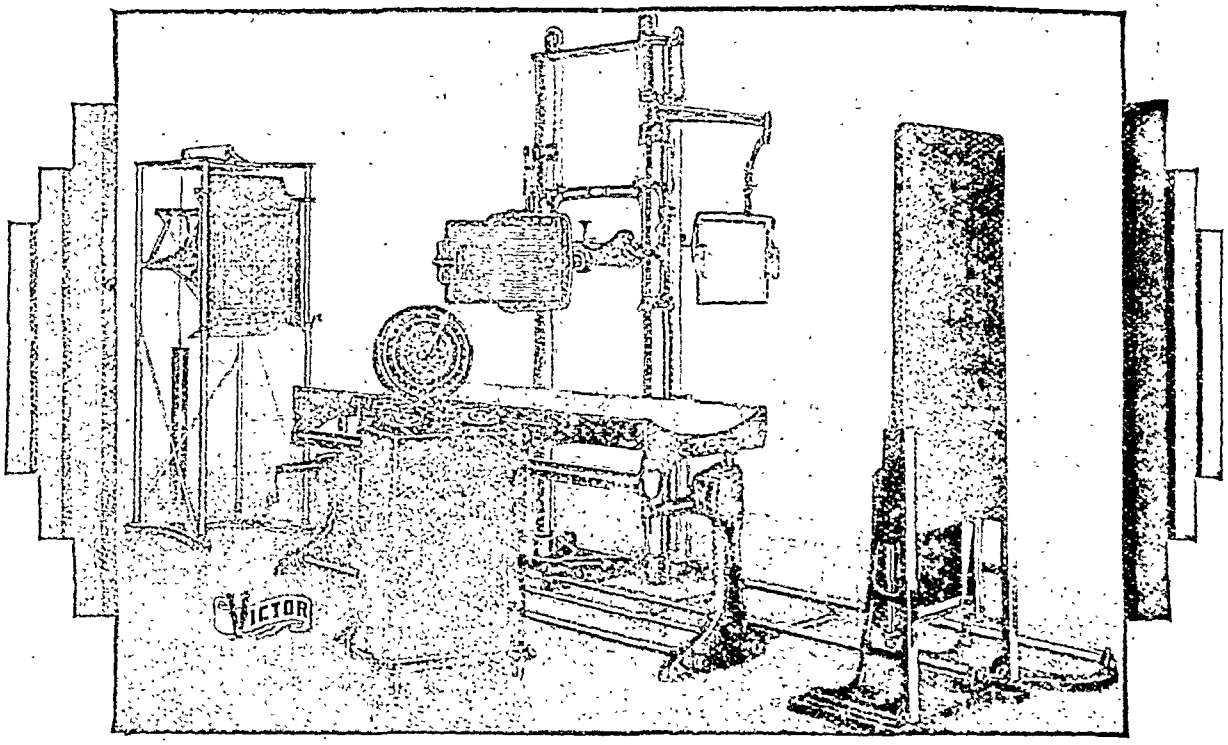
Fitted with 24 Lenses (+0.5 to +20 and —1.0 to —20.0), which permit the Fundus and Media of any eye to be minutely examined. It is of the Reflexless Type. The illuminating system directs the light through the lower half of the patient's pupil while the fundus is seen through the upper half, thus doing away with the corneal reflex, which is the bugbear of Ophthalmoscopy. Can be used as a TRANSILLUMINATOR and for FOCAL ILLUMINATION.

In cases of Intus the flare of the Albuminous Aqueous can be readily made out, and a diagnosis made.

Ophthalmoscope only

Price, 48/6

In Half-Round Velvet-Lined Case, with spare Battery.



From all Surgical Instrument Makers.

Routine Radiographs of exhibition quality

with the

Victor Shock-Proof X-Ray Unit

IT'S OIL IMMERSED

Other Features:

100% electrically safe.
Silent operation.
Self-contained. Compact.
Greater flexibility.
Increased diagnostic range.
Eliminates overhead system.
Longer tube life.
Not affected by altitude or humidity.
Introduces a new principle of control. Consistent results.
Complete diagnostic service.
Unit construction permits variation according to specialty.
Minimizes danger around ether as when setting fractures, etc.
Few retakes—longer tube life.
Same tube used over and under table

"YES, these are beautiful radiographs, I assure you, but they are to be expected from your own experts who produce them specially for exhibition purposes."

This and similar statements are heard repeatedly at the various medical meetings where the Victor Shock-Proof X-Ray Unit is shown, together with a display of radiographs made with this apparatus.

But step into an X-ray department where they are using the Victor Shock-Proof X-Ray Unit and you will find the regular run of radiographs of an exhibition quality—a quality that is appreciated by the radiologist in making his interpretation.

Never before has an X-ray apparatus been available in which the control factors have been refined to the degree realized in the Victor Shock-Proof X-Ray Unit. With it one may produce a consistently high quality of radiographs simply by following a standardized technic made possible by this ingenious control system and the advantages inherent in the design of the apparatus proper.

The control feature is second in importance only to the safety of this X-ray unit. By sealing the specially designed Coolidge tube and the high tension transformer in the oil-filled tube head, complete insulation is realized and all danger of electrical shock is eliminated.

You will be interested in all the facts about this epochal development, as fully described and illustrated in literature, which we will mail on request.

To Relieve Chronic Intestinal Stasis in Women

When you have a patient with chronic intestinal stasis due to diminished tonicity and stretching of abdominal muscles following a pregnancy, you will obtain excellent results from the mechanical support provided by a Spencer Belt.

Equally satisfactory results are obtained by the use of a Spencer Abdominal Belt for cases where atrophy and diminished tonicity are due to toxaemia and loss of fat following a severe illness or an abdominal operation, or in any case where enteroptosis exists.

SPENCER BELT

The back of the Spencer Belt is made long enough for comfort, and to provide adequate back support.

The front of the garment curves in snugly to the pubic bone, and is so designed and adjusted that it uplifts the abdomen instead of compressing it.

Spencer Belts to relieve chronic intestinal stasis will be provided with ptosis pads if the physician desires it.

Each Spencer Belt is designed to meet the special needs of the individual who will wear it. You can therefore prescribe and obtain exactly what your patient needs.

The Spencer Corsetiere will call at your surgery or at your patient's home to take measurements under your supervision.

We issue booklets on the use of Spencer Supports for the relief of enteroptosis, hernia, movable kidney, sacro-iliac strain, and for maternity wear. We will gladly send you any in which you are interested.

SPENCER

For Special Treatment

Indications include :—Pyorrhoea, Gingivitis, Acne, Angioma, Naevus, Eczema, Epithelioma, Impetigo, Lupus, Psoriasis, Seborrhoea, Ulcers, Prurigo, Prostatitis, Trachoma, Ocular Tuberculosis, Laryngeal Tuberculosis, Ozena, Hay Fever, Nasal Tuberculosis, Tonsillar Infection, etc.

THE KROMAYER BURNER.

The Kromayer Lamp is the ideal apparatus for ultra-violet treatment of small areas of the skin or within a cavity.

"It is maintained that when medical or surgical measures have failed, then ultra-violet radiation is the most effective method of dealing with chronic ulcers . . . . The amazing direct bactericidal power of ultra-violet rays has been demonstrated time and again. Given a source with a high concentration of short wave-lengths, such as the Kromayer lamp, the lethal effect is almost instantaneous."

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: "'Ardente' is a godsend to me"; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, adjusted, and supplied.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

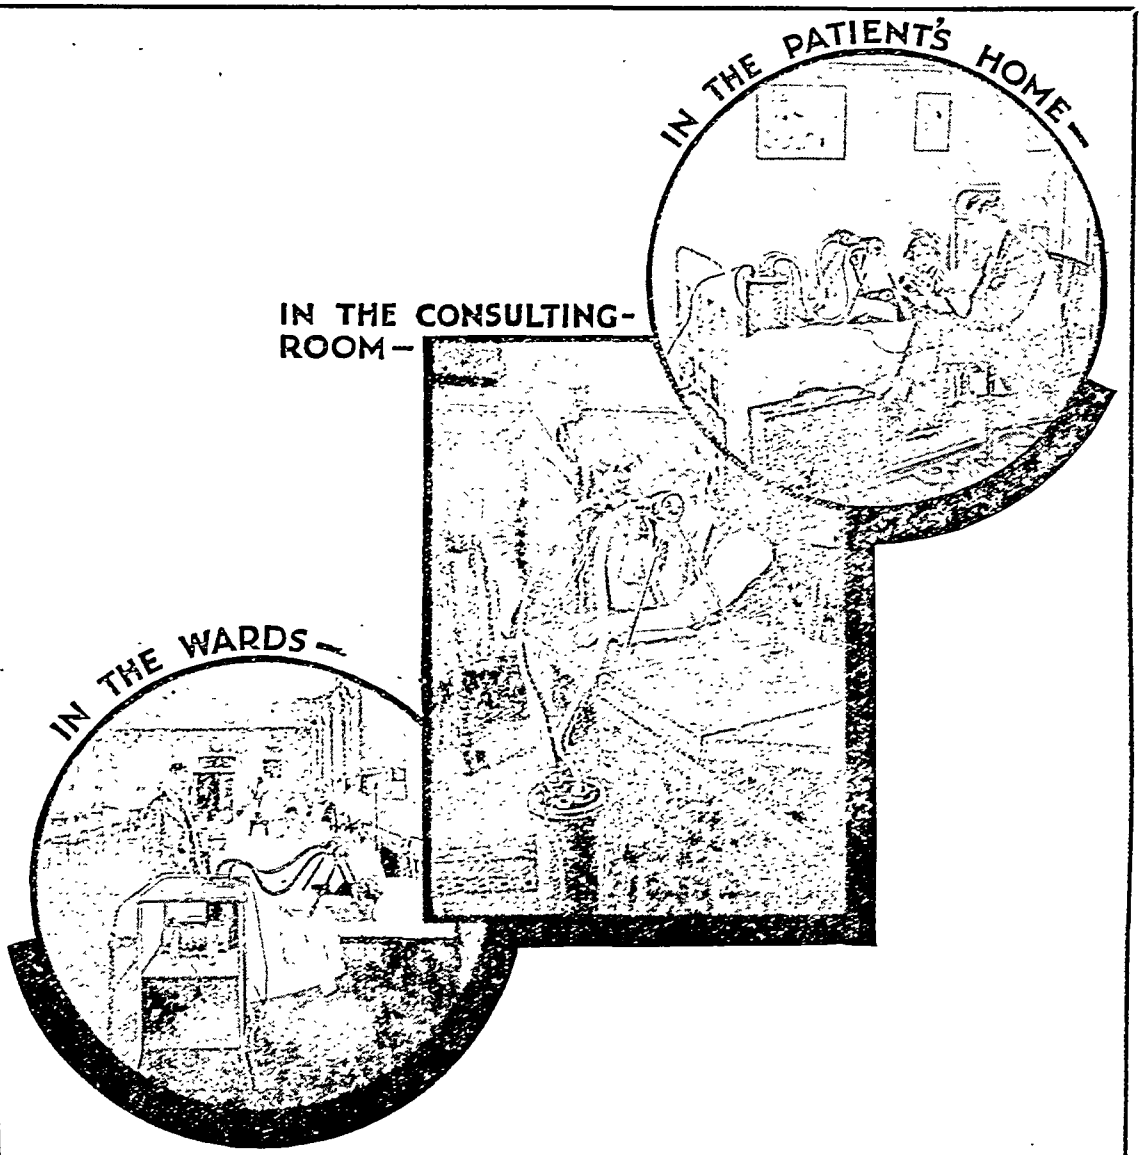
MICKLEFIELD IRRADIATED MILK

Treating the Milk.

By this process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.



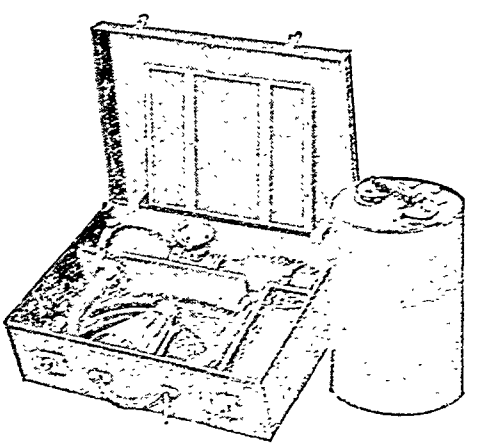
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

Full particulars appeared in an article in the LANCET, January 18th, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every weekday in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.



Doctors everywhere praise the "METALIX-PORTABLE."

Almost daily the number of general practitioners using the "METALIX-PORTABLE" grows larger—once they have acquired the outfit, a wider sphere of usefulness opens up to them—they become "METALIX-PORTABLE" enthusiasts.

In consulting room or patient's home, the "METALIX-PORTABLE" will produce radiograms of remarkable definition which greatly facilitates rapid interpretation.

The doctor need possess no electrical knowledge—there are no complicated controls—no element of danger.

Consider for a moment the possibilities in your practice. Ask us to carry out a demonstration or send descriptive literature.

The Weatherproof for Health

THE BURBERRY

THE BURBERRY

Every Burberry Garment is labelled "Burberrys."

The doctor who wears The Burberry faces every kind of weather confident of being not only perfectly, but healthfully, protected.

The secret of the weather-resisting efficiency of The Burberry lies in

BURBERRYS' SYSTEM OF PROOFING

Burberrys treat the yarn from which the materials used to build The Burberry are woven, *before* they are woven, in a way which renders them, like a duck's feathers, naturally antagonistic to water, so that rain runs off the surface of The Burberry as does water from a duck's back.

Burberry proofing being done *before* weaving, it follows that there is no interference with the natural porosity of the materials.

THE BURBERRY

which is worn with the greatest sense of comfort, and benefit to health, in wet or fine, warm or cold weather, and keeps one perfectly dry in heavy downpour or continuous drizzle, is undoubtedly

The World's Best Weatherproof and One of the World's Best Overcoats

THE BURBERRY BOOK tells the story of the great value of The Burberry, both as a Weatherproof and as an Overcoat. A copy, together with patterns of materials and prices, post free on mention of "British Medical Journal."

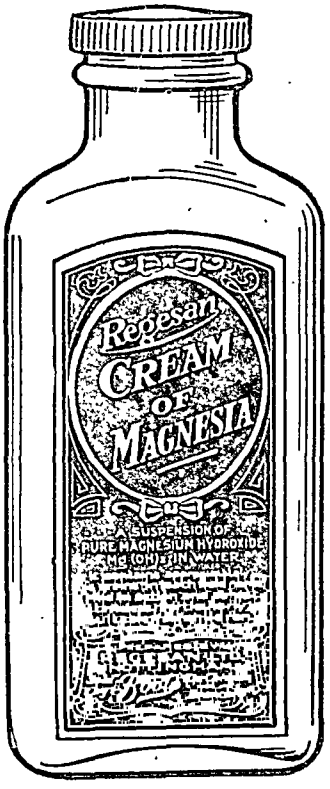
47 Years of Pen Leadership behind the Beauty and Efficiency of Waterman's patrician

Waterman's "Patrician" represents the latest and smartest mode in Fountain Pens. It has the artist-craftsman's touch—like a fine watch in its precision. The "Patrician" is the outcome of 47 years' experience in the making of fine writing instruments. It is a pen of noble proportions. The nib is extra large and wonderfully flexible. There is a new style clip and the mountings also are of pleasing and original design. No fewer than 300 separate operations are necessary to produce this pen de luxe. There are five colours:—Jet, Turquoise, Onyx, Emerald, and Nacre. See this beautifully made pen. Handle it. Write with it. Note its exquisite colouring, its fineness of finish.

Writing Set in Onyx. Pen & Pencil to match. In attractive case
63/-

Ideal for GIFTS



The "Patrician" is a gift that will be welcomed for its beauty and appreciated for its utility. Its price is 42 -. There is a Waterman's "Patrician" Pencil at a guinea to match every "Patrician" Pen. Also Writing Sets, with Pen and Pencil to match, at 63 -, in attractive cases for presentation.

Ask your Stationer, Jeweller, or Stores to show you Waterman's "Patrician" Tray containing the complete series of five pens.

Nacre.

STIMULATING, RAPIDLY ABSORBED, THESE ESSENCES RESTORE VITALITY WHEN SOLID NOURISHMENT IS IMPOSSIBLE

BY APPOINTMENT

RECENT investigation amongst members of the medical profession reveals that 99 *out of every* 100 interviewed recommend Brand's Essences.

Containing those essential elements of meat which excite the gastric secretions and make digestion easier, Brand's Essences provide an immediate stimulant when vitality is low and the body too weak to absorb solid food.

No effort is required to assimilate them, for they consist only of the pure juices of the finest fresh meats conserved in their natural form, without the addition of any preservatives, colouring matter or gelatine.

The delicious jelly is invaluable in dangerous illness whenever a patient is in need of food which can be absorbed without the slightest strain on the digestive organs. And in convalescence, Brand's Essences promote appetite—help to win back the desire for solid, strength-building diet and so hasten recovery.

Brand's Essences are obtainable at chemists and stores throughout the world in tins and glasses. Free samples will be sent to you on receipt of professional card. Write Dept. F6, Brand & Co. Ltd., Mayfair Works, Vauxhall, S.W.8.

The "Allenburys"

"CHARKAOLIN" GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

For Comfortable Anaesthesia

It is now established that the objectionable sequelae often following ether anaesthesia are caused by toxic impurities in the ether employed—*"The purer the ether the better the anaesthesia."*

Not only is purity of manufacture necessary, but it is essential that the ether should be capable of being stored indefinitely without its undergoing any change.

As a result of investigations carried out in the B.D.H. laboratories it has been found possible to produce ether that is perfectly stable and free from all impurities. The absolute purity of Aether Puriss. B.D.H. removes all risks, and renders a comfortable anaesthesia certain on every occasion.

It is not surprising, in view of the foregoing, that Aether Puriss. B.D.H. is regarded as unique in its degree of purity, and that it is being used by a continually-increasing number of anaesthetists throughout the British Isles.

REINFORCED COD LIVER OIL —BOOTS

THE therapeutic value of Cod Liver Oil is fully appreciated by the Medical Profession. It is recognised for its specific action (due to its high content of Vitamins A and D) in rickets, affections of the chest, and diseases arising out of malnutrition. Boots Reinforced Cod Liver Oil is a biologically controlled preparation containing five times the amount of Vitamin D in addition to the normal amount of Vitamin A. The advantage of a concentrated oil needing only a fifth of the usual dose will be particularly valuable. Four fluid ounces of Reinforced Cod Liver Oil —Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil.

In 4-oz. bottles, 2/6.

Peptonised Beef Jelly (BENGER)

and

Peptonised Chicken Jelly (BENGER)

These can be served either in their jelly state with a few biscuits, or dissolved in hot water in "beef-tea" form, making a valuable restorative readily assimilated by weak digestions.

Containing much of the flesh-forming elements of the meat in soluble form, these peptonised preparations are superior in effect to ordinary essences or extracts. Added to soups they considerably increase the nutrient value.

In hermetically sealed glass jars, 2/- and 3/- each.

NOTE.—Benger's Peptonised Beef Jelly and Chicken Jelly are entirely free from preservatives.

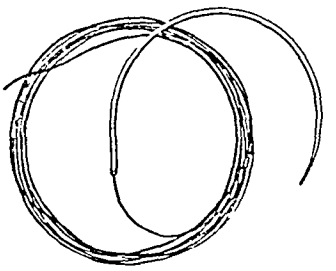
London Hospital Eyeless Needles

WITH L.H. CATGUT



The London Hospital Eyeless Needles have been specially designed to avoid the doubling of the suture necessary in using needles with pierced eyes. They are fitted with tubular ends into which the sutures are firmly fixed, thus enabling the needles to be used with single strands. These needles are finely ground, sharp pointed and packed sterile in tubes for immediate use. Special precautions are taken to avoid any rusting of the needle after it has been packed.

Metatone

A Palatable Vitamin B Reconstructive Tonic

HARDLY a day of a physician's life is passed without one, or more, of his patients requiring a tonic. Metatone is a general tonic particularly suitable for such occasions. In the treatment of general debility, during convalescence, in neurasthenia, anæmia and rickets, after surgical operations and during pregnancy and the period of lactation, Metatone may confidently be prescribed for its reconstructive, restorative and tonic properties.

Metatone is an agreeable fluid combination of vitamin B, nucleinic acid and glycerophosphates, containing in each fluid ounce:—

Vitamin B Extract	10 grains
Nucleinic Acid	2 grains
Calcium Glycerophosphate	4 grains
Potassium Glycerophosphate ...	4 grains
Manganese Glycerophosphate ...	1 2 grain
Sodium Glycerophosphate	2 grains
Strychnine Glycerophosphate ...	1 25 grain

The adult dose of Metatone is one to two teaspoonfuls, three or four times daily, usually after meals.

Supplied in bottles of 8, 16 and 80 fluid ounces.

Streptococcal Conditions

In the treatment of streptococcal conditions Vaccines provide the surest means of reaching deep-seated organs which are inaccessible to antiseptics. Some practitioners, however, are deterred from using Vaccines owing to fear of reactions, but this objection may be overcome by employing Detoxicated Streptococcal Vaccine (Genatosan). In the preparation of this vaccine all the toxic elements of the germ are removed; as a result it is given in both acute and chronic cases without harmful reactions and produces a high degree of immunity.

For the average case a course of five injections is recommended, commencing with an initial dose of 1,000 millions and working up to a maximum of 20,000 millions. Detoxicated Streptococcal Vaccine is polyvalent and is suitable for the treatment of septicæmia, puerperal fever, cellulitis, lymphangitis, and all septic infections of streptococcal origin.

Practitioners interested in Vaccine Therapy are invited to write for a brochure covering the full range of Detoxicated Vaccines, to Genatosan Ltd. (Vaccine Dept.), Loughborough, Leics.

Gastritis, Gastric and Duodenal Ulcer

That BiSoDoL is a therapeutically sound preparation will be readily appreciated from its formula.

BiSoDoL is a balanced combination of the Sodium and Magnesium bases with Bismuth Subnitrate, Carica Papaya, Malt Diastase, and Mentha Piperita.

BiSoDoL supplies a convenient and agreeable product for the treatment of gastro-intestinal conditions associated with hyperacidity. It is a valuable preparation for allaying such digestive symptoms as eructations, flatulence, distension and nausea.

BiSoDoL is also giving excellent results in the alkaline treatment of gastritis, and of gastric and duodenal ulcer as well as in the control of cyclic vomiting, and the morning sickness of pregnancy. In the latter the effect of BiSoDol has been especially noteworthy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

BiSoDoL Limited,
12, Chenies Street, London, W.C. 1.

APPENDICITIS

Impacted enteroliths are frequently found to be the exciting agent in appendicitis, even in cases where the bowels were presumed to have been acting normally. Complete removal of faecal concretions from the caecum and colon is promoted by an occasional course of Andrews Liver Salt, a saline aperient with a Pleasant Taste, Perfect Effervescence and Prompt Action.

It acts by increasing the fluid content of the bowel, causing gentle, painless peristaltic contractions. By stimulating the mucus glands to secrete normally, it does not lead to habit-forming, and is especially useful in the constipation associated with haemorrhoids and hepatic disorder.

Dose: One-half to three teaspoonfuls (according to age and requirements) in a glass of water.

An 8-oz. Tin sent free on request:

SCOTT & TURNER LIMITED, Works and Laboratories at Newcastle-on-Tyne

THE LANCET AND

RYVITA
CRISPBREAD

RYVITA
1930 TALKS
No. 1.

"The Lancet" in its Reports and Analytical Records has said of Ryvita Crispbread:—

"There is more character in the flavour of Rye than of wheat, and the food value of the former (rye) needs no comment.

"On analysis (of Ryvita) the following results were obtained:—

	Per cent.
Carbohydrates, altered starch, hemicellulose, etc.	74.8
Protein	11.6
Moisture	9.0
Ash	1.8
Fat	1.3
Fibre	1.5

Calorie value per lb., 1662.

"Ryvita Crispbread, which keeps well and does not readily become 'slack,' is easily masticated and digested, and is a useful and palatable addition to the diet. The calorie value shows it to be a concentrated form of food."

* * *

Ryvita Crispbread is a most appetising form of bread—crisp, crunchy, and delicious. It is made of pure, crushed, whole-grain rye, and is a complete cereal food, not only because of its perfectly balanced food elements but also because, mechanically, its natural fibrous form is an actual aid to the functional processes of digestion, assimilation, and elimination.

Ryvita is rich in the natural organic salts of iron, phosphorus, and lime, and is therefore a valuable body-building food. It is balanced by its own B Vitamin, because owing to a difference in the structure of rye grain the germ cannot be lost in the milling as it so often is from wheat or oats.

Many Doctors make Ryvita Crispbread their own daily bread, and recommend it enthusiastically to their patients. Ryvita is definitely indicated as an item of the dietary in treatment of disorders arising from digestion, constipation, or malnutrition.

It is usual to suggest that the patient begin by eating two or three slices of Ryvita with one meal each day.

We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

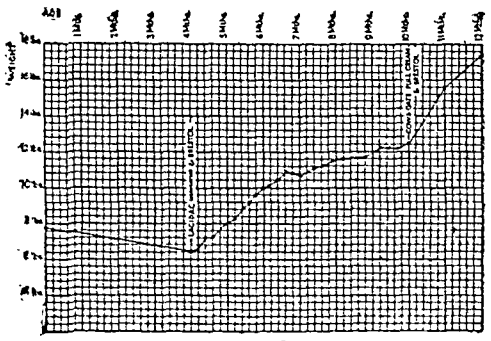
A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs. 9 ozs.) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia. The infant was put on to *LACIDAC* (Separated) with a small quantity of *BRESTOL* and immediately made steady progress.



At 6 months he had gained 3 lbs. 7 ozs. and by the end of another 4 months his weight was 12 lbs. 6 ozs., and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol.

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby.

His Doctor considers him a '*Resurrection.*'

Gastric Dilatation
in relationship to
Vitamin B Deficiency

By "Pathologist"

In our recent work on intestinal stasis, we had noted that not only were the caecum and colon affected by the absence of B vitamin in the diet, but so also were the other portions of the digestive tract, especially the stomach itself. It was, therefore, decided to recapitulate our work, paying special attention to the gastric region of the digestive tract.

Five rats were placed on a diet consisting of rice starch, butter, mineral salt mixture and casein. This diet consisted of a sufficient quantity of protein, carbohydrate, fat and salt mixture, as well as a sufficient quantity of A vitamin. Orange juice was also given for its C vitamin content, and thus the diet was only deficient in B vitamin. Five control rats were fed on a similar diet, except that Bemax was added to supply the B vitamin.

The test was started on March 17th, and after the first month the deficiency rats were going down hill, and 2 per cent. of yeast extract was given, which was just sufficient to prevent the animals from dying, but it did not prevent them from losing weight. On July 11th Bemax rats and the non-Bemax rats were killed. The animals were killed by chloroform, and immediately on cessation of life the abdominal cavity was opened. In the non-Bemax rats peristalsis was found to be absent, but could be stimulated by a sharp tap of the forceps to the caecum; this wave of peristalsis was very sluggish and soon came to a complete stop. In the Bemax rats waves of active peristalsis were seen without any artificial stimulation. The stomachs of the non-Bemax rats were found to be greatly distended, full of food, and placed low in the abdomen.

Figs 1 and 1a are reproductions of actual photographs, and a comparison of these shows the marked difference in size of the "Non-Bemax" and "Bemax" stomachs. The stomachs of the five deficiency fed animals were similarly distended, the distension taking place almost entirely in the cardiac end of the organ. This was noted in all our experiments.

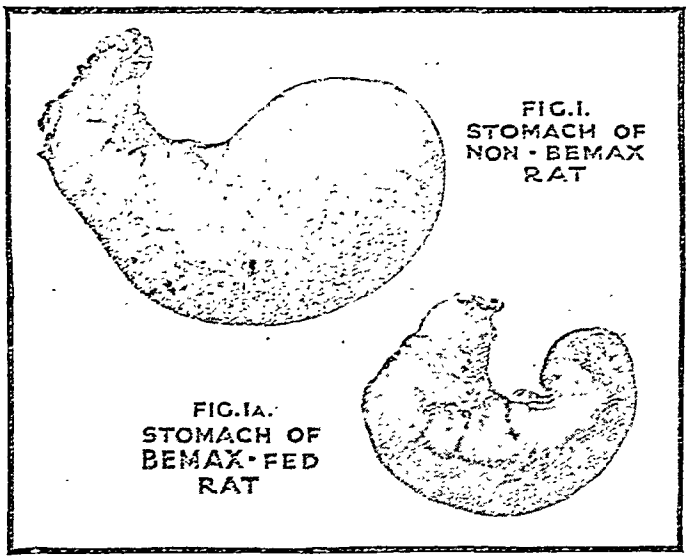

FIG. 1. STOMACH OF NON-BEMAX RAT

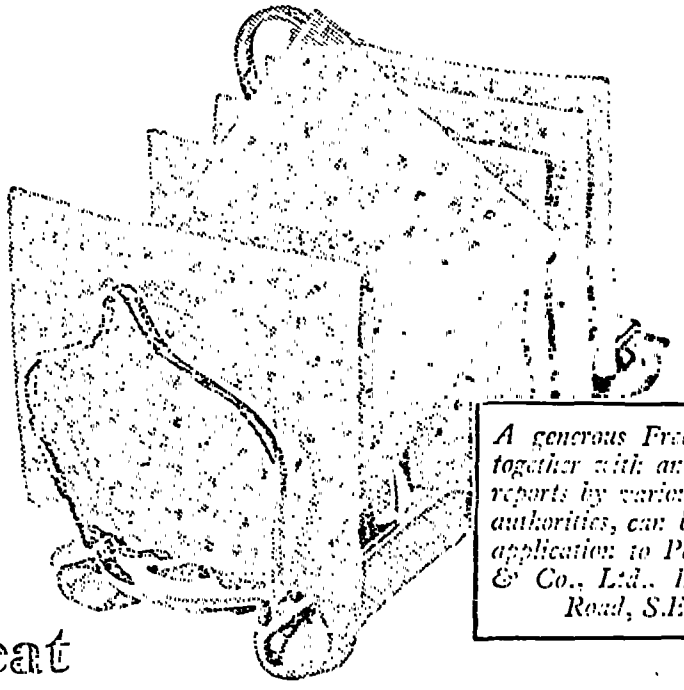
FIG. 1A. STOMACH OF BEMAX-FED RAT

These experiments indicate that the conditions described are undoubtedly brought about by a deficiency of vitamin B in the diet.



Detailed reports of further research work will be sent on request.

BEMAX

Max-imum Natural Vitamin B.

Samples of Bemax for personal test and full reports of the laboratory experiments outlined above will be sent on application to any Medical Practitioner on request to:

THE BEMAX LABORATORIES,

A generous Free Sample, together with analysis and reports by various medical authorities, can be had on application to Peek Frean & Co., Ltd., Drummond Road, S.E.16.

Vita-Weat
prescribed in place of ordinary bread

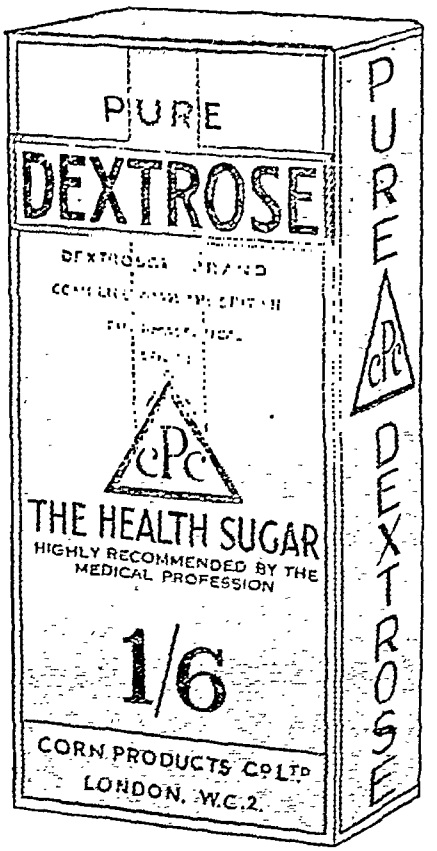
A most agreeable and beneficial alternative to soft wholemeal or white bread, especially in cases where a diet regime is prescribed, is to be found in Vita-Weat, the British whole wheat crispbread.

Vita-Weat presents the whole wheat berry in a *concentrated and digestible* form, with the Vitamins A, D and B in an active condition.

The *Practitioner*, reporting on Vita-Weat in August, 1927, said: "The value of this crispbread is not only in the vitamins it contains, but because it requires thorough mastication, while the branny scales serve *as a corrective to intestinal inertia*."

The *Lancet*, in its report on June 11th, 1927, vouched for Vita-Weat in the following terms: "It will be noted that the caloric value is high." (The *Lancet's* own calculation was 1,846 per lb.) "It has a pleasant texture and flavour . . . . It is undoubtedly a valuable foodstuff, more particularly in respect of its content of Vitamin B."

The Royal Institute of Public Health report, printed in the *Journal of State Medicine*, Vol. XXXV, No. 8, stated that "Vita-Weat crispbread contains all the necessary elements and possesses a good physiological fuel value," and further said that the special method of manufacture "gelatinises the starch grains and thoroughly disintegrates the cellulose, fibre, etc., of the grain, *thereby rendering the finished product completely assimilable*."



These valuable testimonials show that the regular use of Vita-Weat will promote health, vigour and physical fitness.

COLUMN-CAPITALS EVOLVED BY BYZANTINE PIONEER ARCHITECTS.—Prior to this period, the capital had to support only an architrave or lintel. In the new building form the architrave gave place to vaulted arches, and the architect had to design a capital capable of bearing the greater weight and harmonising with the changed superstructure. The Byzantines provided more space for the reception of the arch and added solidity by shaping the cubical block of marble which was to form the capital, so as to give it a rounded base to fit, and harmonise with, the column and a rectangular upper surface, cutting away the intervening portion in carved curves. In this way they formed a number of varieties, among which were the "bowl," the "melon," the "bird and basket" and the "Byzantine Corinthian" types.

A Lecture
ON
JAMES MACKENZIE AND HIS MESSAGE.*

BY
JOHN HAY, M.D., F.R.C.P.,
PROFESSOR OF MEDICINE, UNIVERSITY OF LIVERPOOL.

SIR JAMES MACKENZIE stands out as one of the master minds in medicine: a man who, in the future, will find his place with leaders such as Sydenham, Stokes, Graves, Addison, and Bright. As Sir Thomas Lewis has pointed out, in the *British Medical Journal* of March 15th, James Mackenzie rightly belongs to a distinguished group of men, experimental clinicians—men of Mackenzie's own kidney—Ferrier, Horsley, and Head. He died in January, 1925, and it is now possible, after a lapse of five years, to gauge in some measure, and with some prospect of success, the mark he made on the medicine of his day.

James Mackenzie is the finest example in our time of a general practitioner who by force of character, exceptional intellect, and unremitting industry rose from the ranks of the profession to become an outstanding authority in medicine, with a reputation which is world-wide. The story of his life has been told by Dr. McNair Wilson in a book entitled *The Beloved Physician*, and it is with pleasure that I fully acknowledge my great indebtedness for the vivid and arresting picture he has given us. But, fascinating and illuminating as it undoubtedly is, I feel that his biography hardly does justice to the memory of the man he called master. I would like to convey the impression left on my mind by Mackenzie and at the same time to stress what I believe to have been his message to the profession as a whole, and to the general practitioner in particular—a message which is apt to be missed if one becomes too much interested in the controversial side of his activities.

Born at Scone in 1853, of sturdy Highland farming stock, James Mackenzie was one of a family of seven. These were lean years for farmers, and the Mackenzie family was much straitened. Money was scarce, rents were high, but the hard school of adversity is an environment which makes rather than mars character. His brother, William Warrender Mackenzie, now Lord Amulree, is a most distinguished lawyer, and when he was raised to the peerage the *Times* referred to him as "the greatest living expert on industrial arbitration and conciliation." Another brother, Robert, went into the ministry, he was a man of great literary ability.

James attended the village school, and later the Academy of Perth, where he and his brothers received what every Scots lad of that time received—a sound education: although, if one may judge from his own criticism, he did not entirely approve of the manner in which ability was assessed. So far as I know, he did not distinguish himself in any way. He was not gifted with a retentive memory, nor had he an "index mind," and school honours fall, as a rule, to those who remember rather than to those who think. His was a brain that developed slowly.

For some reason he became fascinated with the idea of being a pharmaceutical chemist; or was it that he was bored with school life, and the chemist's shop was a means of escape? At any rate, at the age of 15 he became a chemist's apprentice at a salary of £5 per annum. He soon realized that he had accepted a mode of life that was monotonous and full of drudgery, but in the five years of his apprenticeship he must have learned a great deal about human nature as he viewed it across the counter—for example, the pathetic belief of the ordinary man in the value of drugs, and the implicit faith of the general public in a "bottle." He came into daily contact with the practitioners of Perth, and there can be no doubt that this period was an admirable training for any man who was to engage later in the profession of medicine.

His apprenticeship at an end, he refused a tempting offer of partnership from his employer—a fine tribute to his character and efficiency—but his mind was now set on becoming a doctor. Before embarking on his university career in Edinburgh he went to Glasgow and worked as a chemist for a year; there, in his leisure, he read for the entrance examination.

At Edinburgh he worked with determination, but it was not until he entered the wards at the Royal Infirmary that he realized that he had come to grips with the real thing. He had left the physiological laboratories and dissecting room behind him, and was at last in direct contact with the sick human being. Here he found scope for his ability, and gained two medals, which must have done something to restore his belief in himself. In 1878 he graduated, and four years later received the degree of Doctor of Medicine.

A medical man who was Mackenzie's junior at Edinburgh and remembers him well once described him to me as a "gaunt, gauche, determined, ambitious youth, who worked like a nigger." I know little about his early career except that after graduation he held a resident house appointment in the Royal Infirmary, Edinburgh, and he told me he was then offered the position of demonstrator in pathology in the university. Of this great opportunity he was unable to take advantage. Financial reasons made it imperative that he should enter general practice. Accordingly he declined the tempting offer, which was accepted by his friend Sims Woodhead, who ultimately became professor of pathology at Cambridge.

GENERAL PRACTICE AT BURNLEY.

In 1879 began the second phase of his life. He left Scotland and became assistant in an old-established practice in Burnley, where he lived and worked for twenty-eight years.

Plunged into practice Mackenzie was at once brought face to face with the same problems with which we have all had to deal. It was not long before he recognized that in the majority of his patients in the earlier phases of illness a full and satisfactory diagnosis was impossible. He had to admit that frequently he did not understand the mechanism of many symptoms and signs, and, what was of more importance, he realized that he could not with confidence assess their significance. A man complained of irregular action of the heart, and asked whether it was a serious matter and should he continue with his occupation. A woman would ask if she was justified in marrying and bearing children. An insurance company required information as to the expectation of life in a man in whom a cardiac bruit was present. Mackenzie had to admit that he was unable to give the required information, and, what was more, no one else could. How did he begin? He did what most of us would have done, and bought books, in the belief that in them he would find the help he needed. But in vain.

An outstanding characteristic of Mackenzie was the fearless honesty with which he defined the limits of his own knowledge. He respected facts not authority. He never hesitated to confess when his knowledge ended and surmise and guesswork began, and he had an uncanny power of defining this limit.

"I put to myself the question: Do I understand the meaning of one single sign or symptom in all its aspects—for example, the mechanism of its production, or the bearing of its cause upon the patient's future health? In this way I was brought to a realization of the fact that I did not understand the full meaning and significance of a single symptom."

He found, for example, that he did not understand the mechanism of such symptoms and signs as pain, the sense of exhaustion, shortness of breath, cardiac irregularity, cardiac murmurs—conditions met with every hour among his patients. Nor was he able to speak with any confidence concerning them in terms of prognosis. He fully understood neither their origin nor their import, and it was not long before he grasped the fact that his fellow practitioners were in no sense better informed. Accordingly he set before himself the task of investigating the nature of the symptoms and signs which he had met with commonly in the course of his practice.

"I had thus placed before me two definite objects at which to aim: (1) understanding of the mechanism of symptoms, and (2) understanding of their prognostic significance. When at this date, forty years after, I look back upon my work I can recognize that it was this simple resolution and these definite aims which guided me to such success as I have achieved."

*The first James Mackenzie Memorial Lecture, delivered at the Institute for Clinical Research, St. Andrews, April 8th, 1930.

He had, therefore, within a few years of starting in practice, clearly defined his aim. He saw that the only way to attain the information he sought was to observe each patient over a number of years and to note how far those presenting certain symptoms or physical signs tolerated illness and the stress of life. This meant years of careful clinical observation and the keeping of detailed records with recurrent analysis of his findings.

It was soon obvious to Mackenzie that it was not possible to do more than focus his attention on a small group of symptoms and wait and see what the future revealed. Certain tragic happenings early on in his practice caused him to interest himself more particularly in the cardio-vascular system, and the early evidences of cardiac failure in pregnant women. Again, the significance and meaning of pain fascinated and intrigued him from the very first, and to this he devoted much time and thought. One of his first publications was a paper on "The study of sensory symptoms associated with visceral disease," which appeared in the *Manchester Medical Chronicle*. Having clearly defined his problem he set out to solve it.

Here, then, is the quest of his life—to understand the mechanism and prognostic significance of symptoms. How did he, "amid the distractions of the life of a busy general practitioner," succeed in reaching his goal? He did it by method and concentration, and still more by pondering constantly on the problems he was investigating; they were ever present in his mind. It meant a careful system of note-taking and routine revision of his findings. Each day he devoted a short time to reading, revision, and thought. At one stage he found the early morning most suitable, before the work of the day began. Later, when I knew him, it was from 9 to 10 on alternate mornings, and during that time he refused to be disturbed. His Sunday afternoons were a kind of field day. Patients in whom he was especially interested would turn in, tracings were taken, records completed. Later, when he was famous, physicians from all over the world would be found at that Sunday clinic in Burnley.

As an all-round general practitioner and a capable surgeon he operated on his own patients—those whose symptoms he had himself watched and noted, often for years. He supervised the period of pregnancy, and carefully studied the response of damaged hearts to the strain of child-bearing. This was his material, his opportunity, similar to that at the disposal of every general practitioner.

The larger number of his patients were cotton operatives, bluff jannock Lancashire folk, who express their likes and dislikes with equal frankness. Mackenzie's downrightness, his bluntness and unselfishness, appealed to them; they trusted him implicitly.

In such a practice there is no time wasted by unnecessary talking. A tap on the door and straight into the sick-room, and within a few minutes Mackenzie had noted the points that mattered, the result of treatment, any change in the heart rate, or temperature; and often a record of the heart's action was made while the thermometer was warming up. No unnecessary fuss, no hot air. Down to essentials all the time.

For a little over a quarter of a century he worked in Burnley, undoubtedly the most important and momentous years of his life. To aid him in the investigation of the cardiac irregularities he first modified the Dudgeon sphygmograph in such a way that he was able to record the venous pulsations simultaneously with the arterial, and finally, with the help of Shaw of Padiham (a genius of a watchmaker), he invented the ink polygraph—a portable machine which enabled him to take long records, doing away with the necessity for varnishing. The greater part of his heart work was, however, carried out with the simpler instrument—the Dudgeon—and the small strips of smoked paper.

In 1902 he published the results of his investigations in a book entitled *The Study of the Pulse*, and from that moment his reputation was made. It was a new landmark in cardiology. A German translation followed, and both on the Continent and in America intense interest was aroused. It was my good fortune to be asked by the editor of the *Liverpool Medico-Chirurgical Journal* to review the book, and I remember how absorbed I became as I mastered chapter after chapter, and realized that it opened a new field for work and investigation. I was, moreover, profoundly impressed by the fact that this important contribution to medicine was made by a man immersed in a large general practice—immersed, but not submerged. A vivid demonstration of what can be done by one who is prepared to take advantage of his opportunities—the opportunities which only a general practice could offer, the material for which lay ready to his hand. In those days the reviews in our *Liverpool Journal* were signed, and a year or two later, when Mackenzie and Professor Wenckebach came over to the Royal Infirmary to visit Dr. James Barr's wards, Mackenzie towered above me, and his first words were: "Are you the John Hay who wrote the review of my book in the *Liverpool Journal?*" I bashfully admitted that I was, and wondered what was coming next, and was more than relieved when he said: "I don't mind telling you that you were one of the few men who had taken the trouble to read my book before they reviewed it." That meeting was the beginning of a friendship which was broken only by Mackenzie's death.

Fame was then in the offing. Honours and distinctions were yet to come, but I believe those were the happiest days of his life. He knew in his bones that his work was good, and that at last his views were finding acceptance all over the world. It is interesting to recall that in 1906 Dr. Arthur F. Hurst wrote:

> "Of all English physicians, the best known and most frequently quoted in Germany is probably Dr. Mackenzie of Burnley, a prophet who has hardly met in his own country with the recognition which he deserves."

However, distinguished men like Osler, Keith, Wenckebach, physicians, anatomists, physiologists, and others, were finding their way to Bank Parade, impressed by the importance of Mackenzie's work, and desirous of meeting the man himself. His reputation had reached far, and his opinion was sought by medical men and their patients, not only from Great Britain, but also from Canada, America, Germany, and France.

It might be thought that a man who accomplished so much professionally would find little time for other interests; far from it. Mackenzie was a first-class golfer, a good chess player, quite useful with a billiard cue, and a no mean hand at cards. He had soon learned that, in a life such as his, concentration was an essential feature if he were to accomplish anything, and this faculty he cultivated. No one better "filled the unforgiving minute with sixty seconds' worth of distance run." He was thus able to make the most of every half-hour devoted to his special work. He was at one with Robert Louis Stevenson, who wrote:

> "Contend my soul for moments and for hours,
> Each is with service pregnant, each reclaimed
> Is like a Kingdom conquered, where to reign."

Mackenzie was blessed, or cursed, certainly dominated, by a restless and inquiring mind. By nature a fighter (it was written in his face) he was most "tenacious of any position taken up until the evidence against it was conclusive." Then he frankly conceded the ground, and from his new position began yet again to probe into the unknown. Lord Moynihan would have said that Mackenzie "dwelt in a land of ever-advancing frontiers."

He was not at his best addressing a large audience. His training had not led to his being a good popular exponent, and he was sometimes accused of want of lucidity. This was due in part to the fact that he failed to realize that his audience did not understand the assured basis on which he built up his exposition. He took their knowledge for granted, and sometimes he did not succeed in holding the attention of the meeting. Professor Wardrop Griffith has brought to my memory the first gathering of the Association of British Physicians, when Mackenzie spoke on his tracings, and, like Scrooge, made "a perfect Laocoön of himself," wreathed in some kilometres of polygrams.

He was best by far in an informal discussion with a few sympathetic and like-minded men, where his premisses were accepted and his downrightness was not misunderstood. In such an environment his enthusiasm was

contagious. I should like to have been one of the small group of men on the liner bound for Canada, in 1906, for the meeting of the British Medical Association—a circle including Ashby of Manchester, Clifford Allbutt, Sims Woodhead, and other distinguished men. With them Mackenzie discussed the whole question of heart-block, and opened his mind on the subjects which held his attention. On his return I remember his childlike delight at the enthusiastic reception accorded to him in Toronto, a delight not so much in his personal triumph as in the recognition and acceptance accorded to his views.

That was in 1906. Two years later, at the age of 55, he had a severe attack of angina pectoris lasting two hours. This was the first manifestation of the dread disease which slowly encroached on his physical reserves, and which, fifteen years later, caused his death. One might mention here, for it is of some medical interest, that his brother, the distinguished clergyman and author, died from angina at the age of 64, and angina also caused the death of a sister.

MACKENZIE'S LIFE IN LONDON.

After twenty-six years of general practice in Burnley Mackenzie decided to move to London. It was admittedly a bold step for a man of 54, but he was eager to enter the medical life of the metropolis and there to expound more fully the views he held. Accordingly, in 1907, he took his courage in both hands and to London he went. The result was a phenomenal success, and is, I believe, without parallel in the history of Harley Street.

For the first year, as was to be expected, his practice was negligible, but his leisure enabled him to finish and publish a comprehensive and liberally illustrated textbook on *Diseases of the Heart*, with which everyone is familiar. It had a remarkable reception, rapidly ran into a second edition, was translated into German, French, and Italian, and was directly responsible for a welcome increase in his consulting work. From then onwards he experienced no further financial troubles.

In London he met with much kindness, and it was not very long before he was on the staff of the Mount Vernon Hospital, and that of the West London, and some years later he was offered, and accepted, a position on the full staff of the great and renowned London Hospital, where he was placed in charge of a fully equipped heart department and appointed lecturer in cardiac research. During the eleven years in which he practised in London he gathered round him men of the calibre of Thomas Lewis, Cushing, Parkinson, Cotton, Windle, Price, and others—all keenly interested in cardiology, and to this group he was a source of inspiration. Essentially a kindly soul, he made friends both in and out of the profession. His life was full of many interests, and his private work overwhelming. But nevertheless he managed to publish books and write numerous papers. He lived at Northwood in Middlesex, and in order to have some leisure for thought he made it a rule to keep Sundays free from all professional engagements, a rule which was only rarely broken.

Then came the great war, and he was swept into the maelstrom. He was asked by the Government to help in organizing one branch of the medical service. It was manifest to all that the medical men of the country had failed to differentiate between organic and functional disease of the heart, and they were unable to assess the extent of cardiac disability, when present. In fact, they did not possess sufficient knowledge to separate the fit from the unfit. There was no one in Great Britain better equipped to give advice in such a problem than Mackenzie. It was the old question which he had spent his life in solving.

If Mackenzie had been asked for some test by which to gauge how far the medical profession of the country had grasped his teaching, how far they had understood the significance of "the response to effort" as an index of the efficiency of the heart, he could not have devised anything more searching than the war. Thousands and thousands of fit men were being rejected all over the country, and the military hospitals both at home and in France were becoming hopelessly congested with cases of so-called heart disease—the beds they occupied being urgently needed for more serious conditions. In desperation the War Office appealed to Mackenzie for help. This he gave ungrudgingly. In collaboration with Sir Thomas Lewis he organized a scheme which was effectual, and must have saved this country some millions of money and rendered efficient thousands of men. Incidentally, it did much to spread among the members of our profession a more accurate knowledge of the diseases and disorders of the heart.

During his residence in London he was the recipient of many honours. He delivered the Oliver-Sharpey and the Schorstein Lectures, and in 1914 the George Alexander Gibson Memorial Lecture in Edinburgh. He was elected Fellow of the Royal Society in 1915, and in the same year he received the honour of knighthood. These and other honours came to him and gladdened his heart. He had good friends in plenty, a life full of interest, of patients more than enough, a delightful home in the country, everything to make a man happy and contented, and he was successful as the world judges success. But there was something lacking; there was a seed of restlessness and dissatisfaction in the mind of this man of more than 60 years. He became more and more aware that the life he was leading in London was a hindrance rather than a help to the working out of the ideas which were ever present in his mind. Conscious of the need for the investigation of the earlier stages of disease, the subjective manifestations of disordered function, he realized that he must be free of his consulting practice and the distractions of life in London. He yearned to be off again on the old quest. At an age when most men are beginning to think of retiring gradually and restricting their activities, this old warrior, conscious of advancing heart disease, is full of plans for a fresh adventure.

ST. ANDREWS.

In 1918 he said farewell to Harley Street, and, at the age of 65, began a new phase of activity in St. Andrews. In this city, small if judged by its population, but great in renown and graced by an ancient and honoured University with a notable School of Medicine, it was not long before Mackenzie had gathered round him all the local practitioners, infected them with his own enthusiasm, and founded an institute. He formulated a scheme for the investigation and prevention of the diseases that are common among the people, a scheme to stir up and encourage research into the earliest manifestations of disease, and he began to organize on a large scale work similar to that which he had carried out alone in his practice at Burnley.

The keynote of his renewed enthusiasm is to be found in *The Future of Medicine*, published in the following year. In this book Mackenzie reviews the present and indicates the lines along which future advance in medicine should proceed.

The methods of the past fifty years have resulted in a great advance in knowledge concerning disease, notably that phase of disease characterized by physical signs—in other words, the later and terminal phase. Our knowledge, on the other hand, of the first and second stages, the predisposing and the early stages, is admittedly most incomplete. These are the stages of symptoms rather than physical signs, and the methods of investigation applicable to the later phases of disease are not wholly applicable to the analysis and elucidation of subjective symptoms. Mackenzie held firmly that this important and relatively unexplored field of research can only be satisfactorily investigated by those in general practice. It is they, and they only, who are in close touch with the patients during the earlier phases.

Unfortunately the education of the medical student is faulty, in that it does not prepare him for dealing intelligently with the clinical material comprising the larger proportion of his practice. He is taught for the most part on patients in whom disease is fully developed, and it is on such patients that he is examined in his final. In short, he is not educated to make full use of his opportunities.

It is a book worth reading, and if at times his presentation of the problem is a little distorted, who can deny that there is much truth in the indictment?

For four years he worked hard here in St. Andrews, organizing the work of the Institute and training his

colleagues in methods of research. Gradually his liability to anginal attacks increased and he had reluctantly to return to the warmer climate of the South of England, physically infirm, but mentally alert, his brain active and critical. In November, 1924, he wrote to me:

"For the last year I have been able to do no work, but it has been the most profitable year in my life, for I have sought for an explanation of the various phenomena met with in clinical medicine. I have been carefully going over physiology textbooks and testing the explanations, and I have got a new outlook on physiological problems."

Nearing his end but, as ever, seeking after the truth, testing the explanations and finding a new outlook. "So with the throttling hands of death at strife, ground he at grammar." On January 26th, 1925, he died in a prolonged attack of angina pectoris.

MACKENZIE'S ACHIEVEMENT.

One may ask, What has Mackenzie accomplished for medicine? Can it be gauged? So much of what he fought for is now accepted and taken for granted. It is, however, beyond question that Medicine has been placed on a different and higher plane by his work and teaching. At a time when the growing tendency is to worship the machine, and when the wonderful technique of the laboratory has become an obsession, Mackenzie has brought back to us a sense of proportion. He invented machines and utilized laboratories, but he never allowed them to blind him to the essentials of clinical medicine. To Mackenzie the bedside of a patient is the place for a physician. He knew only too well that clinical acumen tends to be lessened by a too great reliance on instrumental and laboratory methods. The obsession of the instrument is prone to make us indifferent to the significance of symptoms and unfamiliar with the "face of disease."

Before Mackenzie, our knowledge of irregular action of the heart was chaotic. He analysed the arrhythmias, separated the dangerous from the innocent, defined and distinguished them, and produced order in the place of chaos. From this chaos he dug out auricular fibrillation and rationalized digitalis therapy. This in itself is worthy of a monument.

He blew the old theory of "back pressure" into thin air, though it is true that one still hears of it occasionally from the mouths of those blind to the facts and deaf to the truth. But what is of still greater importance, he taught the real significance of cardiac failure and how to recognize its earliest manifestations, for it is cardiac failure that a doctor fears and must foresee. He proved that the response of the heart to effort, the area of cardiac reserve, is the true touchstone by which to estimate the gravity of murmurs and irregularities, a fact which is still far from finding general recognition.

He spent his life investigating the mechanism of pain, and this study found its final expression in the masterly volume on angina. Important and valuable as are his contributions to the study of visceral pain and cardiovascular disease, he would, I know, have said that they were only *examples* of the method of research which he preached in season and out of season—a method of research applicable to every branch of medicine. His message was a call to the study of symptoms, for better and more intelligent investigation of the patient; he believed in the intensive study of the patient at the bedside, and he held that future progress in medicine depended largely on those who will study the symptomatology of the early phases of disease. It was this belief that in the end led to his dramatic decision to give up his lucrative practice in London and start the Institute at St. Andrews.

There is a certain type of clinical research which from its very nature must inevitably be carried out on patients in the pre-institutional stage—in fact, on patients who are only beginning to feel ill. Such material is in the hands of the general practitioner alone. It is not to be found in the wards of a general hospital, and is not satisfactorily studied in an out-patient department. This pre-institutional research, if it is to yield a full harvest, must be correlated with the type of intensive investigation which is most fittingly carried out in hospitals and associated with laboratories. In other words, the general practitioner must become one of the team; his position frankly recognized and his co-operation welcomed.

You have shown here in your Institute for Clinical Research how this theory can be put into practice. The full realization of your hopes is, I believe, to be found in close co-operation with the School of Medicine here in your great University, and in a lively co-ordination of your clinical activities with the research work carried out in the hospitals of Edinburgh and Dundee. In the complete scheme of clinical research your work is pre-institutional and complementary to that more fittingly carried out in the hospital and laboratory.

The life-history of disease must be followed up and recorded from the first moment of discomfort, the earliest malaise, right on to the post-mortem room. In any such comprehensive scheme work of the type done here in St. Andrews is essential, and to disregard such work will only result in a one-sided and unbalanced conception of disease.

In the realm of Medicine, as in the world of Art, no one can achieve anything of moment whose mind is dominated by greed or who measures success by dividends. Fortunately for our profession, there are many restless eager minds in every branch who are not satisfied to work merely in order to make a living, or for the fun of the thing, or for the pleasure associated with work well done. Such minds find the keenest satisfaction in tackling one or other of the problems which they encounter in their work—problems of prognosis, problems of symptomatology. These men are investigators by nature; they have inquiring minds, they yearn to become, in some real sense, of service to their generation. Unfortunately, many of them are obsessed by the idea that research is the perquisite of those on the staffs of our hospitals, or workers in laboratories, and soon, in the rough and tumble of building up a practice, their earlier enthusiasm fades, and their vision is dimmed. They are entitled to recognition, a recognition which carries with it financial backing and professional status.

To such men the story of Mackenzie's life comes as an inspiration and a stimulus. He is the great example of what can be done and accomplished, not in spite of the burdens of general practice, but in virtue of the very opportunities afforded by such a practice. Let any young practitioner early in his career interest himself in some problem of symptomatology, ponder over it, become familiar with the literature, define as well as he can the limits of knowledge, rid his mind of all that is not fact in relation to it; then collect from the material of his practice those cases which bear on this problem, follow those patients through the years, and I am confident that he will not only add to our knowledge of medicine, but that he will also find in such work both pleasure and an abiding delight.

THE OCCIPITO-POSTERIOR CASE:

*ITS DIAGNOSIS AND MANAGEMENT.**

BY

DOUGLAS MILLER, M.D., F.R.C.S.ED.,

PHYSICIAN, ROYAL MATERNITY HOSPITAL, EDINBURGH; ASSISTANT GYNAECOLOGIST, ROYAL INFIRMARY, EDINBURGH.

THE frequency with which the occipito-posterior case causes difficulty and anxiety in labour is acknowledged by all who engage in midwifery practice. Its importance in this respect is reflected also in the formidable contribution which it makes to what may be called the casualty work of a large maternity hospital. A review of the emergency admissions to the Edinburgh Royal Maternity Hospital over a period of three years shows that approximately one-sixth of the total number have been cases of this kind—a high proportion when the wide variety of obstetrical conditions which may necessitate hospitalization is considered. The extent of dystocia which this complication may produce was illustrated, further, in the discussion on unsuccessful forceps cases[1] at the Annual Meeting of the British Medical Association in 1928, in which it emerged that the cause of failure in almost one-third of 553 such cases was a posterior position of the vertex.

* An address delivered to the North Northumberland Division of the British Medical Association, Berwick-on-Tweed, February 11th, 1930.

A study of the hospital records of a large series of occipito-posterior cases, referred for admission for the most part late in labour, suggests that they may be classed in two groups: first, those in which diagnosis has been at fault and difficulty wrongly attributed, for example, to a contraction of the pelvis which does not exist; and, secondly, those in which the malposition has been recognized, but nevertheless has proved a serious obstacle to delivery. Without comparing statistically these two groups, it may be claimed that the former so outnumbers the latter that certain preliminary and perhaps rather elementary remarks on the subject of diagnosis may be permitted before proceeding to a consideration of the management of this abnormality.

Diagnosis Before Onset of Labour.

The ante-natal diagnosis of an occipito-posterior position by abdominal examination should be a matter of reasonable certainty in most cases, unless obesity or rigidity of the abdominal wall or excess of liquor amnii constitutes an unfavourable condition. Inspection of the abdomen usually shows an absence of the normal uniform anterior convexity, the rounded arch of the back being replaced by the irregular ventral surface of the child, so that a flattening or irregularity of contour of the anterior abdominal wall is produced. Foetal movement may be observed over an unduly wide area of the abdomen, and often on both sides of the middle line.

On palpation the back is difficult to locate, and the irregularity of the small parts is felt more prominently than usual and over a wider area than normal. The head frequently lies in an attitude of imperfect flexion, so that larger diameters than normal are in relation to the pelvic brim. The result of such deflexion is that the head tends to occupy a higher level than usual, and it frequently remains freely mobile after the time that engagement should normally have occurred. Such delayed fixation of the head should always suggest the probability either of contraction of the pelvis or of a malposition of the head; if the pelvic measurements are normal a posterior position of the vertex is without question the most likely explanation.

On auscultation, the foetal heart beat is heard far round in the flank and less clearly than usual; if, however, deflexion is pronounced, it may also be noted in the opposite lower quadrant of the abdomen in front—an important finding which will be referred to later.

On vaginal examination the case with which the anterior fontanelle is felt is recognized as a classical sign of a posterior position of the occiput. On the other hand, after labour has been in progress for some time the vault of the skull may be so obscured by caput formation that the differentiation of sutures and fontanelles may be difficult or impossible. Even so, the frontal suture, and therefore the sinciput, can usually be identified in the following way: If two fingers are placed, one on each frontal bone, it will be found that these bones can be moved each on the other at the frontal suture, whereas, as the result of moulding, such mobility cannot be elicited at any other suture line in the vault. The frontal suture can be palpated only if the position is posterior, and therefore, if the bones on either side of a suture can be moved one on another, that suture is necessarily the frontal suture and the position must be posterior. While this sign is a useful aid in diagnosis, the exact position which the head occupies may be determined more easily and more precisely by the introduction under anaesthesia of as much of the hand as is necessary to palpate the ear. This is the diagnostic feature on which reliance may most confidently be placed; and it is one of which advantage should invariably be taken as a preliminary to the application of forceps where any doubt exists as to the position of the head.

If forceps have already been applied without an exact knowledge of the position of the head, it should be suspected that the occiput is posterior if difficulty is experienced in approximating the handles of the instrument, if more than moderate traction is required to move the head, if the forceps tend to slip, or if the perineum appears to be stretched by the handles or lower parts of the blades of the forceps rather than by the advancing head. In such circumstances the forceps should be withdrawn at once and the position of the head determined with certainty, and if necessary corrected before the instrument is reapplied.

Treatment Before Onset of Labour.

The statistics of the ante-natal department of the Edinburgh Royal Maternity Hospital show that in rather more than 80 per cent. of cases a posterior position may be converted into an anterior by the use of pads, as described by Bust of Dundee.[2] It is true that pads are not successful after engagement of the head has occurred; on the other hand, their ineffectiveness in such cases is of less account, since engagement implies, as a rule, a satisfactory degree of flexion, and therefore the probability of spontaneous forward rotation of the occiput during labour. The type of case in which pads are most useful, and at the same time very generally successful, is that in which there is delay in engagement of the head—for example, during the last week of pregnancy in a primigravida. Such delay signifies relative extension of the head and augurs the possibility of early rupture of the membranes, slow dilatation of the cervix, and a long, difficult labour, terminating possibly in a persistent occipito-posterior: it is the avoidance of such difficulties by ante-natal correction of the malposition that has made the employment of pads such a useful addition to our treatment of the occipito-posterior case. While the pads are in place the patient should be encouraged, when resting, to lie semi-prone on the side opposite to that occupied by the child's back, so that the action of gravity may supplement that of the pads in bringing the back and head round to the front.

Treatment After the Onset of Labour.

It is very generally true that the extent of difficulty in labour which a posterior position may cause is commensurate with the amount of deflexion of the head. In the majority of cases flexion is satisfactory, so that the head engages normally, the membranes remain intact until towards the end of the first stage, the occiput first reaches the pelvic floor and rotates spontaneously to the front: in other words, the course of labour is affected only to the extent that the long internal rotation of the occiput increases by an hour or so the duration of the second stage. In such cases, therefore, the management of labour differs from that in primary anterior position only in two minor respects: In the first place, the longer duration of the second stage necessitates the exercise of more patience than usual, and a careful watch must be kept for such signs of maternal or foetal distress as may call for relief. In the second place, the patient is instructed to lie on the *same* side as that occupied by the back of the child: in this way the occiput is forced down towards the pelvic floor so that it becomes the leading part and rotates to the front.

It will be observed that posture in occipito-posterior cases differs according to whether the head is free or not: if the head is free the object of posture is primarily to favour rotation of the back and indirectly that of the head: the patient lies, therefore, on that side opposite to the back of the child—for example, on her left side if the position is right occipito-posterior. If, however, the head is engaged, an attempt is made to encourage indirectly the forward rotation of the occiput by placing the patient on that side which will promote the advance of the occiput towards the pelvic floor—that is, on the same side as that occupied by the back of the child. It is sometimes recommended that efforts should be made to increase flexion by direct pressure on the sinciput with the fingers in the vagina: such manipulations, however, have the disadvantage that they are difficult and, to be effective, must be carried out over such a long period that there is considerable risk of introducing infection.

In a minority of cases, comprising possibly 15 per cent., flexion of the head is imperfect to the extent that the course of labour is influenced adversely, and in proportion, as a rule, to the amount of deflexion which is present. Such lack of flexion may, in the first place, arrest or delay the head at the pelvic brim, or, at a later stage, may result in the occiput remaining obliquely posterior or rotating backwards into the hollow of the sacrum.

Arrest at Pelvic Brim.

Although delay at the pelvic inlet is not uncommon, it is only in a small proportion of cases, unless a pelvic contraction coexists, that progress is seriously impeded at this level. When this occurs manual rotation of the head should be carried out. No attempt, however, should be made immediately thereafter to complete the delivery with forceps. With the patient anaesthetized the temptation to apply forceps "tentatively" is hard to overcome, but while the head is still free it is difficult to obtain a secure and safe forceps application; moreover, with rare exceptions, the cervix in such cases is still incompletely dilated, so that to follow up correction of the malposition at this stage by the immediate application of forceps necessarily commits the attendant to a formidable operation which may end in failure or disaster. In this type of case, accordingly, after the head and body have been rotated, no further immediate intervention is advisable, nor in most cases is it necessary, for, in contrast to the previous delay, progress is, as a rule, gratifying and sometimes dramatic.

Arrest on Pelvic Floor.

Posterior rotation of the occiput into the hollow of the sacrum almost invariably causes an impasse which Nature cannot overcome, and when it occurs an attempt should be made to relieve the obstruction as soon as its nature is recognized.

The manœuvre of manual rotation, first described by Smellie nearly two hundred years ago,[3] is now so familiar that it is unnecessary to do more than summarize briefly the more important points in its technique: (1) The patient is placed preferably in the lithotomy or crossbed position. (2) That hand is employed which can most conveniently grasp and rotate the head—for example, the left hand in a right occipito-posterior position, and vice versa. (3) Before rotation is attempted the head should be dislodged upwards a little and flexed, so that it may turn more easily. (4) An attempt should be made simultaneously to rotate the body by external manipulations or by passing two fingers of the hand in the vagina beyond the head and on to the anterior shoulder of the child. (5) To maintain the head in the corrected position the right blade of the forceps may usefully be introduced first, instead of, as is usual, the left, in cases in which the head, after rotation, tends to slip back into the posterior position.

In exceptional cases the head may be so firmly embedded in the tissues of the pelvic floor that manual rotation fails. In this event an attempt may be made to effect rotation of the head with forceps, the instrument thereafter being reapplied and delivery completed; alternatively the head may be extracted face to pubes. The former of these methods is advocated by many, but to be achieved successfully and safely demands a high degree of manipulative skill, and most writers insist that this operation should be attempted only by the expert. In less skilled hands a deliberate delivery face to pubes is probably attended by less danger of serious injury to the soft parts and to the child. In such cases extraction is materially facilitated and the extent of soft tissue injury controlled by an oblique perineotomy on one or on both sides.

It will be conceded, I think, that the uneasiness with which one contemplates the occipito-posterior case in general has its origin in the difficulty which a persistent occipito-posterior may cause. This is illustrated in the following table, which refers to patients delivered in the Edinburgh Royal Maternity Hospital.

TABLE I.—*Analysis of 770 Cases of Dystocia due to the Occipito-Posterior Position.*

	Termination.	
	Spontaneous Forward Rotation.	Failure to Rotate.
Maternal mortality	Nil	2.0 per cent.
Foetal mortality...	2.7 per cent.	22.3 ,,
Puerperal morbidity	6.5 ,,	22.3 ,,

It is further true that mal-rotation is not seldom the culminating embarrassment in a labour which from its commencement has been tedious and difficult, and it should be emphasized again that the primary cause of such difficulty is imperfect flexion of the head. It is important, therefore, to attempt to assess, as far as is practicable and at as early a stage as possible, the degree to which flexion is satisfactory or otherwise, for in this way the case in which mal-rotation of the occiput is likely to occur may often be recognized in advance. Deficient flexion may occasionally be suspected before engagement occurs by noting that the occipital and sincipital prominences are equally pronounced and at the same level at the pelvic brim, while vaginal examination may reveal descent of the sinciput in advance of the occiput with caput formation far forward at the vertex. These signs, however, are difficult to recognize and interpret unless the conditions are favourable and the attendant is experienced in abdominal and vaginal examination. More precise and reliable premonitory evidence is available at an early stage in about 80 per cent. of those cases in which anterior rotation of the occiput fails to occur. This consists in the presence of one or more of three phenomena, each of which is directly due to the relative extension of the head. An analysis[1] based on 750 occipito-posterior cases treated in the Edinburgh Royal Maternity Hospital showed that:

1. In cases in which the membranes ruptured prematurely the occiput remained posterior in 74 per cent., while spontaneous forward rotation occurred in only 26 per cent.

2. In cases in which there was delay in the engagement of the head the occiput remained posterior in 77 per cent., rotating forwards in only 23 per cent.

3. In a third group the foetal heart was heard not only in the flank, but also in the opposite lower quadrant of the abdomen in front, pointing to an attitude of deflexion with throwing forward of the chest towards the mother's anterior abdominal wall; in 76 per cent. of these cases assistance was required because of non-rotation or mal-rotation, the occiput going forward in only 24 per cent. Where the groups overlapped, so that two or more of these signs were present together, the occiput remained posterior in rather more than 80 per cent. On the other hand, the normal mechanism was observed to occur in rather more than 90 per cent. of the cases in which the head engaged normally and the membranes remained intact till towards the end of the first stage of labour.

TABLE II.—*Analysis of 750 Occipito-Posterior Cases delivered in Edinburgh Royal Maternity Hospital.*

	No. of Cases in which Noted.	Termination.	
		Mal-rotation or Non-rotation.	Spontaneous Forward Rotation.
Early rupture of membranes ...	197	145 (74%)	52 (26%)
Delayed engagement of head ...	139	107 (77%)	32 (23%)
Foetal heart also anterior	103	78 (76%)	25 (24%)
Normal engagement and rupture of membranes at or near full dilatation of os	332	33 (10%)	299 (90%)

Summary.

The practical bearing of these observations on the treatment of the occipito-posterior case may be summarized as follows:

1. Delayed engagement of the head, especially in the last week of pregnancy in a primigravida, implies relative extension, which may interfere with descent and ultimately produce mal-rotation of the occiput. The value of Buist's pads consists in the fact that it is precisely in this type of case which is potentially troublesome that they are most frequently successful.

2. Where the head engages normally and the membranes remain intact till towards the end of the first stage a satisfactory degree of flexion may be inferred, and it is probable that the occiput will rotate forward spontaneously if given time. In this group, which comprises the majority of occipito-posterior cases, conservatism may confidently be practised.

3. In the majority of persistent occipito-posterior cases there are clear indications at an early stage of labour that this complication is likely to occur. It would appear reasonable, therefore, where such warning signs exist, to anticipate the difficulty associated with backward rotation by correction of the mal-position at or near the commencement of the second stage of labour—that is, before the head becomes firmly embedded in the tissues of the pelvic floor. Such intervention is called for in not more than approximately 10 per cent. of all occipito-posterior cases, and is warranted only when a diagnosis of faulty flexion can be made with certainty. In these, however, the avoidance of needless suffering and of the difficulties and dangers incident to the management of the impacted mal-rotated head seems to justify a departure from the policy of conservatism otherwise so generally applicable.

GLANDULAR FEVER.

BY

GEOFFREY EVANS, M.D., F.R.C.P.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL;
AND

W. A. ROBB, M.D., M.R.C.P.,
CHIEF ASSISTANT, ST. BARTHOLOMEW'S HOSPITAL, AND PHYSICIAN, ST. JOHN'S HOSPITAL, LEWISHAM.

WHEN glandular fever develops in its characteristic clinical form it is easily recognized by its epidemic character, its tendency to affect children and young adults, its sudden onset, persistent fever, mild constitutional disturbance, swelling of the lymphatic glands and spleen, and lymphocytosis. In any case of persistent fever, therefore, especially when there is enlargement of lymphatic glands, the possibility of glandular fever needs to be borne in mind.

The disease may present considerable difficulties in diagnosis when it appears sporadically, as it did at the beginning of the present epidemic, and these difficulties are accentuated by the varied clinical forms which the disease may take. In fact, cases of glandular fever may differ so much from the usual form of the disease that they have been described as infectious mononucleosis and benign lymphoblastosis, while others have been regarded as examples of lymphocytic reaction to acute local infections, chiefly of the upper respiratory tract. Longcope,[1] for instance, in reporting ten cases of the disease in 1922, was of the opinion that there was no proof of the identity of glandular fever and infectious mononucleosis. Tidy and Daniel,[2] on the other hand, maintained the identity of these several conditions, and in a critical review Tidy[3] came to the conclusion that there was no evidence of sepsis as a cause of lymphocytosis. By his observations of the disease Tidy has done much to establish it as a clinical entity, and a monograph recently published by Glanzmann[4] supports his view.

In the present epidemic we have seen twelve cases of glandular fever, and through the courtesy of our colleagues we have notes of several others. Although the main facts of glandular fever are adequately described in current textbooks, and have lately been concisely put together by Dr. Tidy,[3] we have been impressed by the difficulties which may be experienced in making a diagnosis in the absence of a differential blood count, and particularly with the similarity to paratyphoid infections which some cases show.

Description of an Illustrative Case.

A female, aged 38 (patient seen with Dr. F. B. Hobbs). The onset was sudden on March 25th, with aching pains in the head, neck, and back, symptoms of slight respiratory catarrh, and, in general, the sensation of having an attack of influenza. She felt feverish on and off for four days, but the temperature was not taken until March 29th, when it was found to be 102° F., and she took to bed. The temperature chart, which begins on the fifth day of the disease, shows the long-continued fever and its somewhat irregular course until the seventeenth day, after which it shows the characteristic morning remission and evening rise (Chart 1). The pains disappeared after a few days in bed, and, apart from profuse sweating at night and a slight feeling of malaise with the evening rise of temperature, the patient felt remarkably well during the rest of the illness. A papular rash like that of typhoid fever appeared on the trunk on the tenth day, and continued to appear for four or five days. The tongue was coated. There was slight constipation and abdominal distension. The pulse rate was 82 to 92. A Widal reaction on the fourteenth day was negative. Enlargement of the cervical glands was noted on the fourteenth day, and the possibility of glandular fever was first suggested. A blood count made on the following day showed an absolute lymphocytosis.

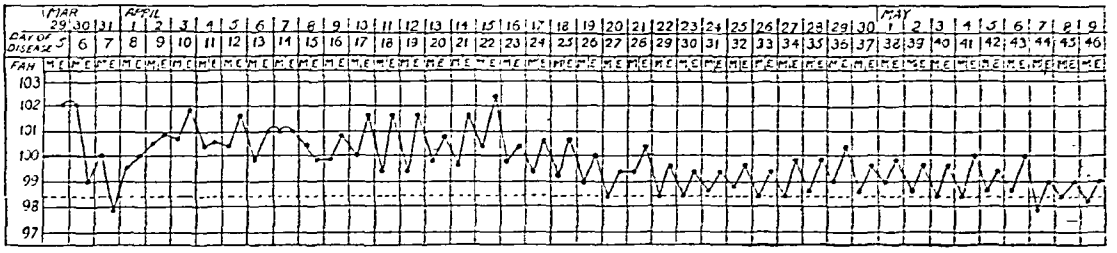

CHART 1.

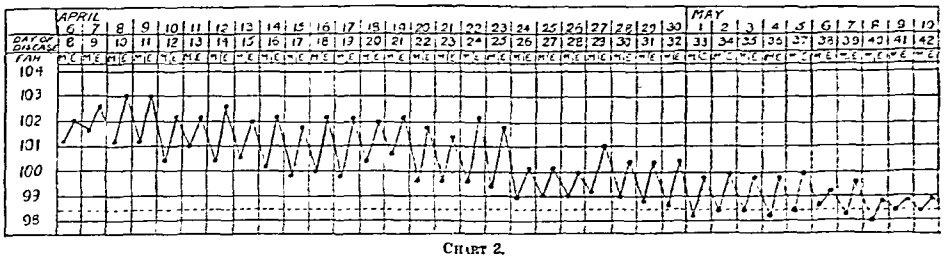

CHART 2.

Discussion.

This case illustrates many of the main features of the disease in our experience of the present epidemic.

The disease appears as an acute infection with a sudden onset, but with relatively slight constitutional disturbance. The regular morning remissions of temperature are well shown in Chart 2 (the case of a girl, aged 15, seen with

Dr. A. J. Williamson). A fall of temperature towards the end of the second week with a subsequent rise about the eighteenth day has been observed in three cases; this fall of temperature requires notice, because it may give the impression of recovery, which is falsified by the subsequent rise of temperature and renewed swelling of the glands (Chart 3, the case of a girl, aged 19, seen with Dr. R. J. Knight). The pulse has been somewhat slow in relation to the fever; its frequency is 84 to 96, and it remains much the same in spite of the marked variations of morning and evening temperature. Thus in one case the pulse frequency was 88, with a temperature of 103.8° F.; it is a little sudden in its rise, full, and easily compressible, and these features persist during at least the early stages of convalescence, when the temperature has returned to normal. The respiration rate is 20 to 24. There is a little upper respiratory tract catarrh and an occasional rhonchus in some cases. There is a little over-action of the heart, a blurring of its sounds, and a slight increase of its size as determined by percussion. The urine often contains a trace of albumin.

The glandular enlargement generally appears early in the disease, but in some of our cases it has not occurred until late, or it has been so slight as to escape notice; thus in 6 cases no glandular enlargement was noted until the tenth, fourteenth (2 cases), seventeenth, eighteenth, and nineteenth day of the disease. The cervical lymphatic glands are most frequently enlarged, those on the left side more than those on the right, and quite characteristically a single circular, rather than oval, gland in the left

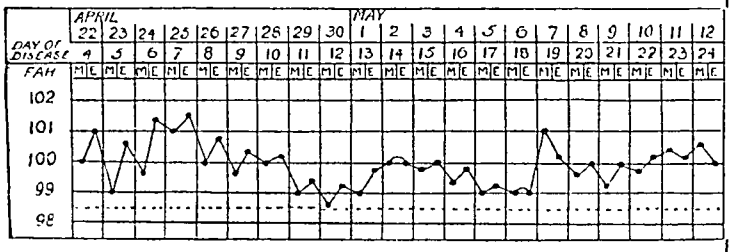

CHART 3.

posterior triangle behind the sterno-mastoid in about the middle of its length. The lymph gland enlargement may be very general, or only single groups of superficial glands may be affected. The glands are discrete, firm, and elastic; they are not painful, but some of the swollen glands are tender on pressure; they somewhat resemble lymphadenoma to feel, but are less tense. The pain in the neck may indicate affection of the deep cervical glands; an irritating or paroxysmal cough may indicate pressure on the bronchi by swollen glands. It was interesting that in one case the diagnosis of enlargement of the mediastinal glands had been made simply on the physical signs of slight increase of the paravertebral dullness and slight obstruction to the right bronchus at a time when the diagnosis of glandular fever had not occurred. Enlarged mesenteric glands have not been palpable, but the abdominal distention has suggested their involvement in some cases.

There is no typical rash in glandular fever. Various rashes are described. In one of our cases a macular rash appeared for twenty-four hours on the fourth day; in two cases there was an urticarial rash; in five cases we have seen a papular rash of which the spots closely resemble those of typhoid fever. These spots differ from rose spots in being somewhat darker in colour and more easily palpable; they have been seen to appear as early as the fourth day and as late as the fourteenth; they may be widely scattered as in typhoid, and three or four spots on the face and a few on the upper arms and thighs and one or two below the knees have been seen in three cases; they are chiefly distributed over the trunk, and more on the front than on the back; they leave a tiny brown stain, which is present for a few days after the papular rash has disappeared.

The enlargement of the spleen is inconspicuous. At best it is easily felt a fingerbreadth below the costal margin on inspiration, in other cases it is hardly palpable, or its enlargement may only be made out by percussion. The liver may be slightly enlarged.

The blood picture is the most characteristic feature of the disease. In our cases the highest white cell count was 22,400, of which 14,400 were mononuclear cells. This was the only case with an increase of polymorphonuclear cells (8,000). The mononuclear increase in this epidemic has been in the form of lymphocytic increase, but in other cases we have seen there has been a striking increase in a variety of immature forms resembling large mononuclear cells with a big, rather pale nucleus, oval, circular, or slightly reniform, and a large amount of pale protoplasm surrounding it, in which are a few azure granules. The polymorphonuclear cells have been normal in numbers, or reduced to 2,600, 2,900, 3,100, and in one case to 1,200. The red blood corpuscles and haemoglobin are normal.

Differential Diagnosis.

It is obvious, from the foregoing description of cases we have seen in the present epidemic, that the difficulty of distinguishing glandular fever from the enteric group of infections may be considerable. The points of similarity shown by some cases are the persistent fever with few physical signs, the relatively slow pulse frequency in proportion to the temperature and the character of the pulse itself, the furred tongue, abdominal distension and tendency to constipation, the enlargement of the spleen, and papular eruption; occasionally epistaxis and respiratory catarrh increase the similarity of the two diseases. Though the onset of the enteric group of infections is typically insidious it is sometimes sudden, especially in paratyphoid fever. The onset of glandular fever with headache, slight shivering, giddiness, and malaise closely resembles paratyphoid fever with sudden onset. The course of the two diseases may also be alike. Thus, though the characteristic temperature of glandular fever seems to be remittent, we have one chart in which it was continuous during the second week; a remittent type of fever is, of course, characteristic of typhoid and paratyphoid fever during defervescence.

The chief points in which glandular fever differs from enteric infections are the lack of constitutional disturbance in glandular fever (apart from the malaise at its onset and the malaise accompanying the evening rise of temperature), the enlargement of the superficial lymph glands, the tendency to sweats, and the lymphocytosis. The negative points are the negative Widal reaction and blood culture.

No one of these diagnostic criteria has absolute value, for, though we have not seen a case of glandular fever in which there is no glandular enlargement, it would seem from the experience of others that this may possibly occur. In some of the cases of glandular fever reported by Tidy and Daniel[2] there was no absolute lymphocytosis at some stage of the disease; and, on the other hand, it is known that infections of the enteric group do not always give a positive Widal reaction as usually performed. When, in addition to this, it is realized that some authors[3] doubt the presence of a rash in glandular fever it may be open to question whether the cases with a roseolar eruption which we have described as glandular fever really belong to that clinical entity. While hesitating to make a dogmatic assertion on this matter, we think that there is good reason to include our cases under the name of glandular fever because of the glandular swelling and absolute lymphocytosis. The other common conditions in which lymphocytosis occur—namely, leukaemia, whooping-cough, undulant fever, and some forms of tuberculosis and syphilis—have been excluded in our cases. Lastly, the presence of roseolar eruption has previously been described in glandular fever; Longcope gives a record of one case; Glanzmann reports another case observed by Königsberger, and also one seen by himself.

THE ASSOCIATION BETWEEN GALL-BLADDER LESIONS AND HEPATITIS IN THE HUMAN SUBJECT.*

BY

E. R. FLINT, F.R.C.S.,

SENIOR ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY.

(*With Special Plate.*)

SINCE E. A. Graham published his paper entitled "Hepatitis, a constant accompaniment of cholecystitis" in *Surgery, Gynecology, and Obstetrics*, in 1918, articles have been written by others corroborating his contention.

The present investigation was begun about three years ago to determine, if possible, the extent of the hepatitis, the type, and the route by which the liver becomes affected. My method has been much the same as that used by others—namely, to obtain segments of liver at operation and to subject them to microscopic and bacteriological scrutiny—but I think my investigation has this advantage over any other within my knowledge, that sections have always been taken from both lobes of the liver, in the case of the right lobe at a distance of at least 1 inch from the gall-bladder fossa, so that the whole liver should not be judged from the condition of that part of it in the immediate neighbourhood of an inflamed gall-bladder.

The method employed to obtain the liver sections was as follows: A triangular piece with a base of about half an inch and sides rather longer was taken from the anterior edge of the right lobe under strictly aseptic precautions and placed in a sterile tube; the sides of the gap were brought together by one or more mattress sutures of fine catgut and tied with just sufficient tension to stop bleeding. A similar proceeding was conducted on the left side. In most of the cases the gall-bladder was sent for examination, care being taken to prevent bile coming in contact with the exterior. In many cases the cystic gland was also separately removed. A fresh set of instruments was used for each proceeding, each specimen being placed in a separate sterile tube; all were sent immediately to the laboratory for culture and later for histological examination. There was never any difficulty in arresting haemorrhage, and the procedure did not seem to disturb the progress of the patients in the least.

There are 50 cases in this series, but for various reasons it has been possible to get a complete histological report of only 34. Of the 34 cases the gall-bladder was pathological in 20 and normal in 14. These 14 cases were regarded as controls, and were operated on for the following conditions: 1 for subacute appendicitis, 2 for chronic appendicitis, 2 for visceroptosis, 4 for duodenal ulcer, 3 for jejunal ulcer, 1 for gastric ulcer, and 1 for a condition needing laparotomy.

THE EVIDENCE OF HEPATITIS: ITS CHARACTER AND EXTENT.

Investigation into the state of the liver was made in three ways: (1) macroscopic—at operation; (2) microscopic; (3) certain liver tests were made before operation and the results placed side by side with those furnished by examination of the liver sections.

Macroscopic Evidence.

There is ample evidence of hepatitis in that part of the liver in contact with an inflamed gall-bladder, but when one attempts to assess the condition of the liver as a whole from naked-eye appearances I think one is on very uncertain ground. In acute infections of the gall-bladder and other organs, such as the appendix, one gets the impression that the liver is large, soft, and succulent, as though it were oedematous, and the rounded edge of the liver lends support; it is difficult to prove, because if oedema is present it is not of sufficient intensity to show in the sections. As regards the more numerous chronic cases I came to mistrust macroscopic observations concerned with thickness and enlargement as evidence of hepatitis, for in many cases these disagreed with microscopic conclusions. In fact, only the latter give reliable evidence; moreover, the information obtained by this simple procedure may be of considerable value in certain cases in connexion with their subsequent progress, when taken in conjunction with liver tests.

Microscopic Evidence.

Under the microscope these cases of hepatitis show round-celled infiltration in the portal tracts and between the liver lobules (Figs. 1 and 2). Fatty infiltration is common, and occasionally degenerative changes suggesting necrosis are seen. The portal tracts often show fibrosis. Polymorphs can be seen in some of the sections, but for the most part the cellular infiltration is caused by lymphocytes. Figure 3 shows a section of normal liver from a case of so-called visceroptosis; the difference between this and Figures 1 and 2 is very noticeable. Two further points are very evident in these sections: (1) the appearances are always of the same character, but differ in degree in different cases; (2) in any one case these characteristics are always the same in degree and kind in the two lobes of the liver; in fact, they are widespread.

As regards the gall-bladder, there is lymphocytic infiltration in most of the coats, sometimes polymorphs, and, as a rule, fibrosis replacing in many cases the muscular coat in part. Strawberry gall-bladders I have referred to as pathological rather than instances of cholecystitis, since the evidence of inflammation is sometimes exceedingly scanty. An analysis of the 34 cases is given in Table I.

TABLE I.

Hepatitis.	State of Gall-bladder. Normal.	Pathological.
None	3	1
Slight	5	7
Moderate	5	2
Marked	1	10
	14	20

There was hepatitis in 30; in 4 the liver sections were normal. Of these 4 cases one had a pathological gall-bladder in which there were no stones, but moderate fibrosis with round cells here and there. The other 3 had normal gall-bladders; one was a case of chronic appendicitis, another of jejunal ulcer, and a third of visceroptosis. At the other end of the table we find 11 cases showing marked hepatitis; there were 10 with pathological gall-bladders, and one was normal; this was a case of duodenal ulcer in which the degree of hepatitis was quite well marked. In the groups showing slight or moderate hepatitis there are 9 cases with a pathological gall-bladder, and 10 in which the gall-bladder was normal—practically an equal number in each class. The most striking features of this table are, I think, the preponderance of pathological gall-bladders in the group with marked hepatitis, and the prevalence of hepatitis whether the gall-bladder is diseased or not.

Of the exact relation of the round-celled infiltration to the structures in the liver, I am uncertain whether it begins in connexion with the bile ducts, lymphatics, or blood vessels; obviously it must be one or more of the three. It seems to me that as a general rule the area near the blood vessels is less involved by round cells, and I think the same may be said of the larger bile ducts. The smaller bile ducts, however, appear to be very definitely placed in close relation to the areas of maximum infiltration, and it is difficult to escape the conclusion that they are in some way concerned; in fact, the condition seems to be a pericholangitis of the smaller bile ducts at the periphery of the lobules in the first place (see Fig. 4). I think a careful examination of the sections shows that the lumen of the bile ducts is free from epithelial debris or other sign of inflammation, and the walls too, though they appear to be pressed against one another, do not show any inflammatory change. It is not easy to be sure of this, because in many sections the ducts are to a great extent obscured by the round cells; but in the clearer parts of the fields it seems to be as just stated. The infiltration surrounding the smaller bile ducts appears to be quite sufficient in many

* An Arris and Gale Lecture, delivered on February 21st, 1930.

places to produce pressure and obstruction; the significance of this will be discussed after reviewing the results obtained with the liver tests.

If it is true that the bile ducts are not actually inflamed, it seems likely that the lymphatics are the real centre of the infiltration and that they run in close relation to the small bile ducts at the periphery of the lobules, and that it is in virtue of this close relationship that the bile ducts are seemingly so much concerned in the infiltration. Practically nothing is known of the lymphatics in the liver: it is therefore only possible to speculate about the position they occupy; but if we compare the lymphatic arrangements in the spleen and lymph glands we find a marked similarity of general plan of structure. In these the reticulo-endothelial tissue sifts out what is not acceptable to the blood, and by means of masses of round cells—in reality the same thing as the solitary glands of the intestine—such foreign matter as bacteria is rendered harmless, and a great proliferation of round cells may occur in and around these masses during the performance of this task. It is therefore suggested as a reasonable inference from what is seen in my sections showing hepatitis that the Kupffer cells, the reticulo-endothelial tissue of the liver, extract harmful material from the blood and pass it out to lymphatics lying alongside the hepatic cells and small bile ducts; thence it is carried to larger lymphatics in the portal sheaths where these abut on the periphery of the liver lobules. If this explanation is correct the masses of round cells seen in my cases of hepatitis may be a reactive proliferation of lymph follicles normally lying diffusely scattered through the liver in a similar though not so well-defined arrangement as that of the lymphatic glands and spleen. In Hodgkin's disease such lymphatic collections become very apparent in the liver.

My series does not provide sufficient material from which to form conclusions as to the route by which the liver and gall-bladder became infected. There are, however, interesting bits of evidence. For example, in one case the liver showed the usual round-celled infiltration, and from both lobes a few colonies of a coliform bacillus were grown; the appendix showed signs of a recent inflammation, and from it was grown a similar coliform bacillus. The patient was a boy of 15, who had recently had an attack of undoubted clinical acute appendicitis, which was subsiding. This would appear to be infection of the liver from the appendix, more especially as the organism, which was identical from the two sources, was not the usual *B. coli*, so that coincident infection of the liver from some other source does not seem a reasonable assumption. There is every reason, too, to suppose that the organisms had been carried in the portal blood. I profoundly mistrust any theory which seeks to explain infection by the lymphatics if it involves the supposition of retrograde flow in the absence of obstruction to the normal forward movement; and so far as the liver is concerned all the lymph normally flows out of it and none whatever into it.

Another case suggests infection of the gall-bladder via the hepatic artery.

This patient was a woman, aged 28, who, until she had an attack of acute tonsillitis, had enjoyed good health. During this attack she was seized with sudden severe pain in the epigastrium, which radiated to the back; there was tenderness over the gall-bladder region; but there was no jaundice. She had several attacks of typical biliary colic later; no indigestion was present in the intervals. At the operation, which was performed two years after the initial attack of pain, she was found to have a thick-walled gall-bladder, shrunken and recently inflamed, which contained a single mixed cholesterin stone. Under the microscope the gall-bladder showed extensive lymphatic infiltration of its wall, the muscles replaced to a large extent by fibrous tissue, and in places large collections of leucocytes. The liver sections showed slight lymphocytic infiltration.

It is reasonable to suppose that the reaction in the liver which we are calling hepatitis results from infection carried by the hepatic artery or the portal vein. As I shall show presently it is unusual to be able to grow organisms from the liver sections; this may be explained partly by the phagocytic activity of the Kupffer cells rapidly weakening and destroying the bacteria, partly by the probability that the noxious material is often toxin and not bacteria, and partly by the surgical habit of delaying operation on acute gall-bladder conditions as a general rule, so permitting time for the lessening of bacterial virulence.

I have already stated that hepatitis is commonly present in many intra-abdominal lesions; it is not quite clear why it should be more marked in patients with pathological gall-bladders than in others. I think that it is, and there are several possible explanations.

1. It may be that the greater degree of hepatitis is primary, and an associated alteration of biliary secretion, in the presence of some metabolic change—as, for example, increased cholesterol in the blood—favours the deposition of aseptic stones, which subsequently, in one way or another, induce cholecystitis and attendant mixed stones.

2. The blood from the gall-bladder is poured into the portal vein close to the liver, whereas that from the appendix, for example, has to travel some distance in a fairly sluggish stream with some 10,000 leucocytes to the cubic centimetre (there may be many more in an acute attack), where there would be opportunity for bacterial virulence to be diminished before the liver is reached.

3. The size of the gall-bladder as compared with the appendix would presumably mean more noxious material entering the liver during a state of inflammation.

These explanations are contingent on infection entering the liver by the portal vein.

4. The hepatic artery may be the portal of entry, the site of infection being a distant focus, and a selective affinity determining the intensity of the attack falling on the gall-bladder as is now generally held. This receives support from the experimental side, but I doubt if we are reproducing human etiological conditions by massive intravenous injection of organisms. Moreover, the supposition would be that the gall-bladder so infected produced the hepatitis; but the degree of pathological change in the gall-bladder does not seem to be the only determining factor in the degree of hepatitis, for examination of 21 cases shows that in 11 a marked degree of cholecystitis and hepatitis coincided, whereas in 10 no such similarity of pathological change was observed—in about half the gall-bladder was grossly changed and the liver little affected, while in the other half the liver showed marked hepatitis and the gall-bladder only a slight degree of inflammation (Figs. 5 and 6). This suggests that sometimes, at any rate, hepatitis is primary.

5. Infection might pass into the liver up the bile ducts; but as the larger bile ducts certainly, and I think also the smaller ones, show no evidence in the lumen or wall of infection it does not seem probable that this is the route by which infection enters and becomes effective, apart from those cases which present partial or complete obstruction of the common duct.

In 32 cases the condition of the pancreas was noted. It is easier to assess the state of this organ by palpation, I think, than in the case of the liver. In 20 patients, 12 of whom had pathological gall-bladders; the pancreas was normal. In 12 others it was decidedly hard, the hardness in most cases being confined to the head; in one of these the hardness was associated with a strawberry gall-bladder, in 2 with very slight cholecystitis, in 2 others with acute cholecystitis, and in 7 with definite chronic cholecystitis; of these 6 were cases of stone in the common duct. It seems probable from recent work on pancreatitis that cases associated with stone in the common duct receive the infection directly up the duct of Wirsung. If we subtract the common duct cases in my series there are 6 left showing pancreatitis out of 24 cases with pathological gall-bladders, exactly 25 per cent., and although the degree of pancreatitis, estimated by palpation, does not tally case by case exactly with the degree of hepatitis estimated by microscopic examination, yet there is a close parallelism. The blood supply to the head of the pancreas comes via the gastro-duodenal artery from the hepatic, which makes this coincidence of hepatitis and pancreatitis an interesting one, and possibly suggests that at least in 25 per cent. of cases infection of the liver arrives by the hepatic artery. Of course this is pure speculation stimulated by the figures and observations recorded above, but it suggests lines on which further investigation might prove profitable.

BACTERIOLOGY OF THE LIVER, BILE, AND GALL-BLADDER WALL.

The results are shown in Table II.

TABLE II.—*Result of Cultures from the Gall-bladder Wall, Bile, and Liver Sections.*

Normal	—	—	Negative
,,	—	—	,,

The outstanding features of this table are: (1) The large number of negative results in all the material examined. (2) In the few cases where the findings were positive the liver sections and bile showed the same organisms only once—a case in which *B. coli* and staphylococcus were cultured from both sources. (3) When positive results were obtained the organisms in the majority of cases were those which normally grow in the intestines.

The simultaneous presence of *B. coli* in the bile and gall-bladder wall in several cases suggests infection of the latter from the bile, for in five out of eight cases of acute cholecystitis *B. coli* were cultured from both, whereas in only four out of thirteen chronic cases were cultures of this organism obtained. There is a strong suggestion here that the infecting organism is *B. coli*, and that it readily dies out; whether it gains access to the bile and the gall-bladder from the liver or up the common duct cannot be decided. The infrequency of positive cultures from the liver suggests the latter route; and further, that if hepatitis is related to cholecystitis in a primary capacity it is so by virtue of inefficiency of the bile to hold its constituents in solution, thereby facilitating the formation of gall-stones and ultimately cholecystitis. But there is the possibility that, although the liver rapidly destroys the virility of the organisms, yet in the presence of inefficient liver cells (shown by liver tests, as we shall see later) active organisms are allowed to go through these cells instead of being rejected by them and passed into the lymphatics.

On several occasions cultures were made from the cystic gland in cases of pathological gall-bladder; only twice did any organism grow—once a staphylococcus and once a streptococcus which conformed to the type described by A. L. Wilkie. This was a case of acute cholecystitis with a stone impacted in the neck of the gall-bladder. In another case in which a man was operated on for a subacute attack of cholecystitis with stones, the cystic gland was about the size of a moderate-sized broad bean. No growth was obtained either from it or from the gall-bladder, although one would think that a gland of this size examined during the actual attack would be an ideal one from which to culture an organism.

The marked pathological changes found in the liver and gall-bladder, combined with the number of negative bacteriological findings, suggest a readiness for the infecting organisms to die out, or it may be that we are apt to place too strong an emphasis on the infection theory of gall-bladder disease. It seems reasonable to infer from these results that it is unlikely that the gall-bladder can be a chronic focus of *bacterial* infection for more distant parts, as the organisms disappear very quickly after they have stimulated the gall-bladder into an inflammatory state.

The media used for culture purposes were: (1) glucose agar—deep tubes; (2) surface smears on blood agar (heated); (3) deep tubes of agar containing 0.1 per cent. sodium sulphide—giving anaerobic conditions.

CERTAIN LIVER TESTS IN RELATION TO HEPATITIS.

For this part of my subject I chose the van den Bergh test, because it is generally considered to give reasonably accurate information about bilirubin and the processes involved in its production, etc., and the laevulose test because it has been well recommended by some and thoroughly condemned by others, and it seemed a good opportunity to find out, if possible, which opinion was justified.

Van den Bergh Test.

The results of this test depend on the quality and quantity of bilirubin in the blood. In obstructive jaundice there is a prompt direct reaction; in haemolytic jaundice a positive indirect reaction only; and in toxic jaundice a biphasic result—that is, a positive indirect and also usually a delayed direct.

There was only one case of clinical jaundice at the time of operation included in my series, as I did not feel justified in taking sections in this type of case as a rule; this case gave a prompt direct reaction. There were three which gave a delayed direct and positive indirect reaction; two of these were common duct cases without clinical jaundice. All the other positive results were of the indirect kind and of varied degree. I have attempted to give the results of the test side by side with the degree of hepatitis as shown by the microscope. For this purpose I have put into one class the cases showing marked or moderate (that is, definite) hepatitis, and into another those showing slight hepatitis or normal liver (see Table III). From this table it will be seen that in the first group the reaction is definitely more pronounced.

TABLE III.

,, ...	D.N.; I.P.		
,, ...	D.P.; I.P.		

D.N. = Direct van den Bergh, negative. D.P. = Direct van den Bergh, positive. I.N. = Indirect van den Bergh, negative. I.P. = Indirect van den Bergh, positive. (s) = Slight reaction. (vs) = Very slight reaction.

It is a little difficult to interpret these results, but there are some significant features. In describing the microscopic sections I have already said that one gets the impression that some of the smaller bile ducts are compressed: this is supported by the delayed direct reaction seen in three of

the cases. Moreover, in some of the sections the liver cells show bile staining, and there are appearances of the same kind as those seen in cases of toxic jaundice. These features suggest that the increase of bilirubin in the blood is due to interference with the polygonal cells, sometimes by poisoning, sometimes by damming back of the bile in the smaller bile ducts, and sometimes by both. The increase of bilirubin shown constitutes latent jaundice. In the few cases in which the fragility of the red cells was examined it was found to be normal; this strengthens the view that the jaundice is due to something in the liver and not to haemolysis.

Laevulose Test.

The basis of this test is that laevulose given to a normal person does not increase the blood sugar, whereas when the liver is functioning deficiently there is a characteristic increase in blood sugar. The dose of laevulose is given on an empty stomach, and the blood sugar estimated half-hourly for two hours.

I have divided the cases into two classes (Table IV) as in the van den Bergh test. In Tables V and VI, dealing

respectively with cases in which hepatitis was marked or moderate and others in which it was slight or *nil*, the results of both tests are placed side by side. One case, which was thought to be an instance of haemochromatosis, should be omitted. It will be observed that there is a close parallelism between the results given by the two tests; on the whole the state of the liver is shown more accurately by the laevulose test. This came rather as a surprise. I do not wish to stress these findings unduly, because the number of cases is small. So far as I know neither of these tests has been checked by microscopic liver examinations prior to this series, and it may be that the condemnation which the laevulose test has suffered is due, not so much to it being an unreliable test of the state of the liver, as to the fact that a result which indicates hepatic deficiency does not necessarily receive clinical support. This may be because our present knowledge of what is going on in the liver purely from clinical observation is depressingly deficient, and not because the laevulose test is at fault.

I feel that some explanation is due for presenting so few cases; I would point out that it is extremely difficult for a single investigator to produce a large series; the work involved is very time-consuming, and it is not always easy to get the necessary collaboration at the time the material comes to hand; moreover, the patient has to be considered primarily, and in many cases I did not feel justified in prolonging the operation beyond the period that was absolutely essential, nor in subjecting the jaundiced patients to a possible risk of oozing from the cut liver, and so on. However, every series adds to the total contribution to this subject, and a sufficient number of cases have been reported, I think, to warrant the conclusion that *hepatitis is associated in some way with cholecystitis*, and also with many other intra-abdominal lesions. In regard to the existence and type of the hepatitis, my findings agree very closely with those of Graham; on the other hand, the bacteriology of my series differs from his in degree rather than in kind; on both these points they are quite different from what A. L. Wilkie describes.

The correlation of functional tests of the liver with microscopic examinations has opened up a new field so far as I am aware; with such a few cases at one's disposal any explanation of the observed phenomena must to a large extent be speculative. Nevertheless, the results seem sufficiently interesting and uniform on the whole to make it worth while extending this method of research.

I should like to thank Dr. A. L. Taylor and Miss Hickman, who did the microscopic part of this work; Professor McLeod and Miss Wheatley, who are responsible for the bacteriology; and Dr. Fowweather, who determined the liver function tests. Without their help it would have been impossible for me to have obtained the reliable laboratory information so essential to this kind of investigation.

CARCINOGENIC SUBSTANCES AND THEIR FLUORESCENCE SPECTRA.

BY

E. L. KENNAWAY AND I. HIEGER.

(Cancer Hospital Research Institute, London.)

(*With Special Plate.*)

THE results described here are the latest obtained in an investigation of the carcinogenic action of coal tar. It has been known for many years that cancer could be produced by certain industrial products (gas-works tar, shale oil) which had been exposed to high temperatures, and this process of formation of carcinogenic materials has been extended in the laboratory of the Cancer Hospital Research Institute by heating a variety of substances (acetylene, isoprene, cholesterol; human skin, muscle, and hair; yeast) of which every one yielded products which caused cancer when applied to mice. An attempt was then made to obtain cancer-producing substances at body temperature by reactions which might resemble more closely those occurring in the tissues, when cancer develops naturally, than do changes in a red-hot tube at 700° to 900°.

Schroeter[1] in 1920 described a mixture of high-boiling compounds formed when aluminium chloride acted upon tetralin (commercial tetrahydronaphthalene) at 30° to 40° C. We found that this material was carcinogenic; one of the earliest experiments with it yielded 8 cancers *and 3 papillomas from 20 mice in* 256 days. This mixture of high-boiling compounds will be referred to as "Schroeter" for the sake of brevity. In some preparations

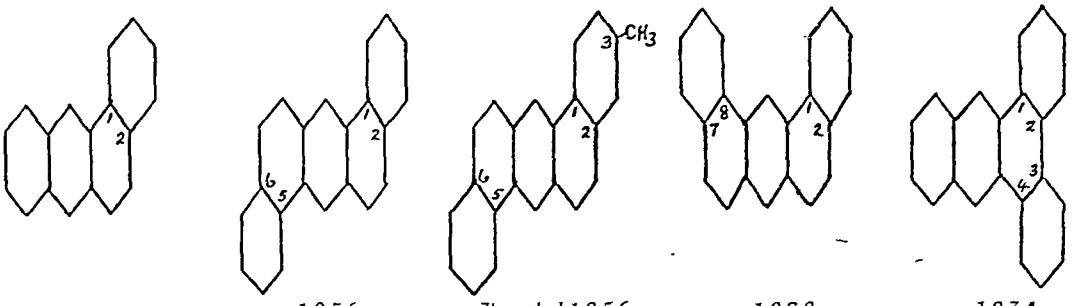
the rather higher temperatures (60° to 70°) used by Schroeter in his subsequent work were employed. Inactive material may be obtained if the aluminium chloride is in too low a concentration, or acts for too short a time. When these negative results are excluded the total yield of tumours from all the experiments with "Schroeter" which gave any tumours at all has been 118 cancers and 30 papillomas in 496 mice. Our later observations indicate that the carcinogenic agent may not be produced in *effective amount* at body temperature, but is increased to the concentration required to cause cancer in the skin of a mouse by the heating necessary to distil off the unaltered tetralin. Hence the original object of these experiments—namely, to produce an active carcinogenic agent at body temperature—may not have been attained, but the developments of this work described below have diverted our investigations for a time in other directions.

Tetrahydronaphthalene is not fluorescent, but the carcinogenic material obtained from it by the action of aluminium chloride shows a blue-violet fluorescence, which becomes very intense in a beam of ultra-violet light. If this fluorescent light is passed through a spectroscope on to a photographic plate a spectrum is obtained consisting of three bands of wave-lengths approximately 4,000, 4,180, and 4,400 A.U.; the bands are sharply defined on the short wave-length side and grade less abruptly into the background on the long wave-length side. The 3,680 A.U. mercury line is used as a fixed wave-length for comparison. A large number of pure hydrocarbons and other substances were then examined by the same methods in the hope of finding one which showed the spectrum of "Schroeter." No identical spectrum has as yet been found. However, one compound—namely, 1.2-benzanthracene—gives three bands which resemble those of "Schroeter" very closely, both in character and in position relative to one another, but in absolute position they lie nearer to the invisible region. Some reasons, which need not be set forth here, suggested that an addition to the benzanthracene molecule might produce the desired shift of the fluorescent spectrum towards the visible, and, possibly, the development of carcinogenic properties also. These additions may take various forms, such as:



1. The attachment to the hydrocarbon nucleus of side chains, which may be aliphatic (for example, the methyl group) or aromatic (for example, the phenyl or benzyl groups). A number of such compounds—namely, the 3-methyl-, 6-phenyl-, 9:10-diphenyl-, and 10-benzyl-benzanthracenes—have been synthesized in this laboratory for the first time by Dr. J. W. Cook, who will describe his methods in the *Journal of the Chemical Society*. Most of these compounds show a shift of the spectrum towards that of "Schroeter," but to not more than one-half of the desired extent. No one of them has as yet produced tumours in mice, but some of them have been under test for a very short time only.

2. The condensation of fresh benzene rings with the benzanthracene nucleus, which itself consists of four such rings. Four such five-ringed hydrocarbons—namely, the 1.2.7.8, the 1.2,5.6, the 3'-methyl-1.2,5.6, and the 1.2,3.4 *dibenzanthracenes*—were prepared in a fairly pure state and applied in benzene solution to mice, and the fluorescence spectra were examined. The 1.2.7.8 and both 1.2,5.6 compounds gave spectra of the "Schroeter" type, but with subdivision of one band; and the whole spectrum lies about [illegible] those of benzanthracene and of "Schroeter." The 1.2,3.4 compound, which may be regarded as differing from the two others in that it is a 9.10 substituted phenanthrene, gives a spectrum of quite different type. The graphic formulae of the compounds are shown below.

Each of these four compounds was applied to ten mice; at the date of writing the experiment has lasted 285 days. The 1.2,3.4 series died out early, leaving one mouse only on the 133rd day, so that no comparison of this compound with the others is possible at present. A second series is under observation. One of the three survivors of the 1.2,5.6 series bears two well-developed papillomas.* Four mice in the 3'-methyl-1.2,5.6 series have produced papillomas. (Figs. 1 and 2.) In the 1.2,7.8 series, the first tumour appeared on the 169th day, when six of the ten mice were still alive; the animal was killed on the 223rd day and the tumour was found to be clearly malignant, showing invasion of muscle over a wide area. (Fig. 3.) Another mouse showed a papilloma on the 222nd day; the tumour grew rapidly, and when the mouse was killed a month later showed obvious invasion of muscle. (Fig. 4.) The last two survivors of the series, each bearing a tumour, were killed on the 278th day; both tumours were found to be malignant. Thus the ten mice painted with 1.2,7.8 dibenzanthracene yielded 4 cancers. The pre-cancerous period is longer than it is in mice painted with a good carcinogenic tar. Our experiments with the dibenzanthracenes will be repeated with larger series of mice and purer samples of the compounds. All such experiments require repetition with very pure material; those who have most experience of hydrocarbons will be the least ready to assert that any sample is quite pure. We have applied a large number of hydrocarbons (naphthalene, α–α–dinaphthyl, β–β–dinaphthyl, α–phenyl naphthalene, cyclohexane, cyclohexene, dodecahydrotriphenylene, acenaphthene, fluorene, anthracene, β-methyl anthracene, octhracene, phenanthrene, retene, truxene, naphthacene, tetrahydronaphthacene, chrysene, and others) to mice with negative results, and we have many other compounds now under test. Hence there are many controls upon the results obtained with the dibenzanthracenes. In the experiments of Twort and Fulton[2] chrysene produced 5 cancers and 10 papillomas in, apparently, several hundreds of mice (the exact number is not stated). The fluorescence spectrum of chrysene is very similar to that of benzanthracene in character, but in position is displaced considerably towards the region of shorter wave-length—that is, away from the "Schroeter" bands.

Apparently neither benzanthracene nor any of its derivatives has been found, and perhaps has not been sought for, in coal tar, and we are at present examining tar, and the products of the action of aluminium chloride upon tetralin, for such compounds. It is quite possible that there are, among the many compounds still undiscovered in coal tar, derivatives of benzanthracene which are far more powerfully carcinogenic than any known substances.

The "Schroeter" bands at 4,000, 4,180, and 4,400 are shown most distinctly by the aluminium-chlori[illegible] tetralin, but they have been found also in the [illegible] spectra of the following carcinogenic materi[illegible]

*One of the tumours borne by the mouse in the [illegible] found to be an epithelioma.

TABLE I.

1. Gas-works tar.
2. Creosote oil.
3. Green oil.
4. Anthracene oil.
5. Pitch distillate.

(2–5: derivatives of gas-works tar.)

6. Heated Californian petroleum.
7. Acetylene tar.
8. Yeast tar.
9. Muscle tar.
10. Cholesterol tar.
11. Hair tar.

If acetylene tar (No. 7) is saturated with chlorine, (*a*) the "Schroeter" bands are shifted about half-way towards the benzanthracene position, and (*b*) the carcinogenic power of the tar is very much lessened. In two comparable series of 70 mice the chlorinated tar produced 4 cancers and 4 papillomas, and the unchlorinated tar 21 cancers and 5 papillomas.

The following substances gave a diffuse spectrum covering very roughly the 4,000–4,400 region without differentiation into bands.

TABLE II.

1. Shale (blue) oil.
2. Pitch.
3. Gas-works tar (a sample made at 600°).
4. Spindle oil.
5. Refined lubricating oil.
6. Blast furnace tar.
7. Unheated Californian petroleum.

Of these, 1, 2, 3, and 4 are carcinogenic, and 5, 6, and 7 are not. The Californian petroleum, when heated to 880°, yields a strongly carcinogenic material (No. 6 in Table I). It is possible that in some or all of these cases the spectrum is confused by the presence of a number of fluorescent compounds.

The following materials gave the same spectrum as those in Table I, but have not produced cancer.

TABLE III.

1. Tetroyl propionic acid mother liquor.
2. Undistilled aluminium-chloride-treated tetralin.
3. Benzyl oleate (technical).
4. Oleic acid (technical).

Two possible explanations of this discrepancy may be suggested—namely (1) that the spectrum is given both by carcinogenic compounds and by allied compounds which are not carcinogenic, and (2) that the fluorescence test is a very much more delicate one than is the production of cancer in mice. Thus some hydrocarbons are fluorescent at dilutions of 1 in 200,000,000. One would not expect such solutions to affect the skin of a mouse. Twort has recorded papillomata in mice painted with oleic acid. Possibly heating of the oil in the process of manufacture is responsible for this effect.

Finally, to complete the list of exceptions, we must record one cancer produced by a non-fluorescent substance. One epithelioma occurred in 30 mice painted with commercial tetralin; we then painted 100 mice with pure tetralin, but obtained no more tumours.

The very frequent recurrence in cancer-producing agents of the fluorescent spectrum described suggests the possibility of the use of it for the preliminary examination of materials, such as lubricating oils, suspected of carcinogenic effect. The test on mice is, of course, necessary for conclusive proof.

All the spectroscopic work described here was carried out by I. Hieger under grants from the British Empire Cancer Campaign. We are indebted to Dr. E. de Barry Barnett for many specimens of pure hydrocarbons used for spectroscopic comparison, and to Dr. Alfred Piney for the accompanying photomicrographs.

A CASE OF DIPHTHERIAL ACUTE MYOCARDITIS STUDIED BY MEANS OF THE PORTABLE ELECTRO-CARDIOGRAPH.

BY

DONALD HALL, M.A., M.D., F.R.C.P.,

PHYSICIAN, ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

In their paper in the *British Medical Journal* of January 18th, 1930, Dr. J. Strickland Goodall and Dr. T. Jenner Hoskin summarize the chief use of the electro-cardiograph as (1) diagnosis or cardio-analysis; (2) estimation of progress under treatment. The electro-cardiograms of the patient who is the subject of this short article were valuable, first, in establishing the diagnosis of acute myocarditis at a time when such could only be inferred from her symptoms in the absence of abnormal physical signs, and secondly, in giving a clear estimation of the condition of the myocardium as it became more severely affected, and then as it made a gradual but steady recovery from the acute inflammation.

The patient was a girl, aged 11, who was removed from the sanatorium of a boarding-school within the Brighton area, and was first electro-cardiographed on October 23rd, 1929, when I first saw her at the Brighton Borough Sanatorium in consultation with Dr. Graham-Bonnalie and Dr. C. Fraser Brockington, the resident medical officer. She was then in the twelfth day of diphtheria, and that morning had developed vomiting with precordial pain. So far as the circulatory system was concerned the only abnormality objectively was a low blood pressure (68/40 mm. of mercury). The cardiac borders and sounds were normal, and there was no interruption of rhythm. An electro-cardiogram, however, which was taken by the Cambridge portable instrument, gave us proof of myocardial affection. All the complexes, auricular and ventricular alike, were of low voltage. The QRS waves were slurred, as well as stunted. The T wave in Leads I and II was shallow and inverted, while in Lead III the T was unidentifiable. The P waves, although small, were identifiable in all three leads, and the P-R interval was within normal limits. The heart's rate was 96.

She was electro-cardiographed again on November 8th, when she gave a record which is the most interesting of all. At that time there was clear evidence of an affected myocardium, the heart being dilated and rapid, with a canter rhythm; the blood pressure was still abnormally low, and particularly the pulse pressure; but as this is one of a series of cases in which Dr. Brockington has made a careful study of the changes of the blood pressure, which he intends to publish, I do not propose to go further into that matter. The electro-cardiogram showed the myocarditis of the left ventricle to be so great that the patient had a right-sided preponderance. The initial ventricular complexes were so low in voltage that they measured a mere 2 mm., but the initial complex in Lead I was an S and in Lead III an R, showing that for the time being the right ventricle was the predominating chamber. The T waves were much as before—in Leads I and II a very shallow inversion, and in Lead III hardly, if at all, identifiable.

On November 29th the electro-cardiogram had again changed. In Lead I the initial ventricular complex was a minute bizarre wave of the type met with in Lead III in a proportion of healthy subjects, but, in contrast to the previous record it contained both R and S elements. The T wave in that lead remained shallow and inverted. There was great alteration in the ventricular complexes in Leads II and III. Voltage had increased from 2 mm. to 11 mm., and there was a definite inverted T wave of ordinary type.

Further changes were noted in the electro-cardiogram of December 12th. In Lead I the small bizarre initial ventricular

complex did not descend at all below the iso-electrical level, being entirely of R type, and for the first time the T wave was easily identified as positive in character. In Lead II the T wave was less steeply inverted, while in Lead III it remained much the same.

On December 30th in Lead I there was a frank upward R wave of a voltage of 4 mm., but a wave which was slurred in its downward stroke; the T wave was still erect but its voltage had doubled. In Lead II for the first time the T wave was positive; but the T wave in Lead III remained inverted, and the curve in that lead was practically identical with that of eighteen days previously.

The patient made a clinical recovery, and a few days later left for Cornwall.

PROLAPSE OF THE RECTUM IN CHILDREN.

BY

IAN FRASER, M.Ch., F.R.C.S.,

ASSISTANT SURGEON, BELFAST HOSPITAL FOR SICK CHILDREN.

ONE cannot attend a children's hospital without being struck by the large number of children who suffer from prolapse of the rectum. No definite treatment is prescribed, and yet apparently these patients cease to return after some time; presumably there has been a spontaneous cure. On referring to the usual textbooks on this subject one finds first the instruction "remove the cause," and yet how seldom one finds a cause.

Etiology.

Constipation is blamed, and with it the straining at stool that is required to expel the solid motion. Diarrhoea has its advocates, on account of the irritation it produces. For a similar reason, worms, polyps, adenomata, and piles are responsible according to others; these, by producing a feeling of fullness in the rectum, would certainly tend to provoke a constant desire to defaecate. An invisible fissure and a symptomless pruritus are often blamed. When a possible cause cannot be found in the anal region recourse is made to some other part; a tight foreskin, a balanitis, or a pin-hole meatus is carefully looked for. Eventually it is said that the real cause is that there is a deficiency of fat in the ischio-rectal fossa, so that the rectum has lost its natural support. On this assumption the condition is similar to that obtained when the perinephric fat is diminished, so that as an analogy we might speak of the condition as a "movable or floating rectum."

The last so-called cause is probably the least likely of all. A close examination of a few of the cases will soon demonstrate that a prolapsus ani is not a prolapse of the anus, but at first of the mucous membrane through the anus. In the early cases the muscle wall of the rectum bears its normal relation to the ischio-rectal fat. Two definite changes exist in the average case: first, the anus is patulous—the examining finger can enter with ease and is not gripped by the sphincter as in a healthy case; and secondly, the mucous membrane has apparently lost its close grip upon the muscle wall, and instead of adhering is carried down with the motion.

Treatment.

As regards treatment, one first looks for a possible cause, and this in the majority of cases is non-existent. Many of the patients are fine, rosy-cheeked, sturdy children; they have regular bowels, have lost no fat recently, and are free from worms, polyps, etc. Having treated the mythical cause, something must be done for the child while he is actually at stool. In some cases the motion is passed in the squatting position, or on the side, and between times the buttocks are held together with strapping. Judging from the fact that patients thus treated stop attending eventually, we must conclude that this method is satisfactory and that in time a cure does result from it; but during that time considerable pain and discomfort must be endured.

I have written this short note with the object of advocating treatment by the injection of absolute alcohol. I have adopted this method in about fifty cases, and cure has followed in all of them. In nine cases out of ten this result has been brought about by one injection; in resistant cases a second injection has invariably been effective. The treatment is not new, but is, I think, insufficiently appreciated; the technique is so simple and the result so good that it is worth trying. The injection of the alcohol stimulates the anus to contract and at the same time produces a fibrosis and adhesion between mucous membrane and muscle.

The procedure is as follows: Without any previous treatment to the bowel the patient is given a general anaesthetic and placed in the lithotomy position. The surgeon places his left index finger in the rectum, and using a 1 c.cm. glass syringe with a fine Record needle, 1½ inches long, he passes the needle through the muco-cutaneous junction along the interval between the mucous membrane and the muscle coat. The injection is made as the needle is withdrawn. Four injections are given at one sitting—in front, at the back, and at each side—the total amount of alcohol used being 1 c.cm.—in other words, 1/4 c.cm. at each of the four points. The operation can be completed in five minutes. The buttocks are then strapped for one day, and the bowels are opened in twenty-four to thirty-six hours. The advantages of this method are that the condition is cured immediately in 90 per cent. of the cases at one sitting, and although the discomfort is greater for twenty-four hours, there is not the summation of pain that the child would otherwise suffer.

In conclusion, prolapse of the rectum is a common and distressing complaint, spontaneously curable in most cases, but reacting readily to a simple minor operation which will save weeks and months of discomfort. A modified technique has been very successful in adults, using novocain instead of a general anaesthetic for the operation itself, and giving some 40 per cent. antipyrin to diminish after-pain.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PATENT BRANCHIAL CLEFT.

(With Special Plate.)

THE case of W. R. C., aged 24 years, presenting a certain feature of interest, appears worth reporting.

This man presented himself with a sinus situated 1 inch above the sternal insertion of the right sterno-mastoid muscle and at its anterior border, which discharged a clear fluid. At the orifice were situated three minute hairs. On injection of the "sinus" with iodoform emulsion the patient complained of sickly sensations in his throat, when examination of the fauces revealed the emulsion lying in the right supra-tonsillar fossa. *X*-ray photographs confirmed the extent of the fistula. In the photographs there appear vague shadows at the level of the disc between the 5th and 6th cervical bodies, suggesting lateral prolongations from the main fistula. It has been impossible to confirm these.

It is significant that the man first became aware of his condition following a right-sided quinsy, when the "pimple" commenced to discharge what was then a yellow fluid.

CONGENITAL DYSTROPHY OF THE NAILS.

(With Special Plate.)

As congenital dystrophy of the nails is comparatively uncommon I thought the following case should be placed on record.

A healthy girl, aged 16 years, was sent to see me with reference to the condition of her finger-nails. Her occupation was that of a domestic, and she said the condition had been present as long as she could remember, but recently the nails worried her by their look and interfered with her work. On examination there was a distinct horny ridge in the mid-line of the dorsum on the nail plates of the middle two digits of both hands, as well as a similar condition of the index finger of the left hand. At the bases of the affected nails the peri-unguinal tissue was raised, but there was no sign of any tenderness. From

this thickened tissue at the nail roots a hard horny ridge extended, which latter tapered towards the ends of the affected fingers.

There was no other congenital abnormality to be found on the rest of the patient except a tendency to a similar condition of the nails of both great toes, though in the latter it was not so well shown.

Leicester. Honorary Physician, Leicester Institution for Diseases of the Skin.

AN EMERGENCY OPERATION UNDER DIFFICULTIES.

LATE one dark night I was called to see a man in a bunk-house. Candle-light revealed on a bunk a very prostrate young man, aged 19, who was violently sick at frequent intervals. He admitted that he had been constipated for two days, and had experienced abdominal pains in severe spasms, and constant vomiting for a few hours. An examination of the patient led to the conclusion that here was a case of acute obstruction of the bowels. The exact site of the obstruction was not clearly defined, but pain, and tenderness over the internal opening of the left inguinal canal, suggested Richter's hernia as a possibility.

An immediate operation was imperative. The nearest hospital was sixty miles away—a full day's journey for a good horseman, over a trackless waste. One cannot ride with acute obstruction of the bowels. A hasty survey of existing premises was made. The local storekeeper lent his office, the cook washed the office floor, and lent a table scrubbed for the occasion from the cookhouse. Several local ladies sacrificed sheets and aprons in order to extemporize dressings, which were placed in enamel basins. The cook roasted the dressings in his oven, while on the stove in a pudding basin he boiled the necessary instruments. An operating team had to be constructed. To the schoolmaster fell the task of administering the anaesthetic, and a motor mechanic, who had once driven an ambulance and therefore held high qualifications, was the chief assistant. The navvy-boss was posted as instrument clerk. The carpenter claimed a right to be present as he had provided the lighting arrangements—namely, two paraffin lamps abstracted from the local gospel hall and suspended from the office ceiling. Surely the conditions for abdominal section were ideal!

Through a left paracentral incision a very small hernia of the anterior wall of the small intestine into the left internal inguinal ring was reduced. The strangulated portion of gut was viable, and was returned to the abdominal cavity and the wound sutured. Recovery of the patient was uninterrupted. The old cook's voice punctuated the stages of the operation. His remarks were addressed to the assistant storekeeper, who had charge of liquid refreshments: "'E's started; what about a little one?" "'E's hinside 'im; what about a little one?" and so forth.

One cannot claim that there is no mental strain attached to opening an abdomen under such conditions, and, at the same time, keeping an eye on so many untrained people, yet the kind co-operation of a community saved the life of a man. This little history may be of some service to those who at some time or other may be confronted with a similar emergency in an Empire outpost.

J. INNES MOIR, M.R., Ch.B., D.P.H.,
Principal Medical Officer, Falkland Islands.

AORTIC ANEURYSM SIMULATING ASTHMA.

IN the following case of aortic aneurysm the symptoms simulated those of asthma, and the true diagnosis was established post mortem.

E. W., aged 43, carman by occupation, was admitted to the West Middlesex Hospital on September 28th, 1929, complaining of cough, which was worse at night. He had had this symptom for two weeks, but otherwise felt well.

His temperature on admission was 98.4° F., pulse rate 108, and respiration rate 28; both his cheeks were flushed. Rales and rhonchi were audible over both lungs, but there were no areas of dullness to percussion in the chest. The apex beat was in the fifth space, 3.5 inches from the mid-line. The heart sounds were clear, the second aortic sound being somewhat ringing. Under treatment the pulse rate and respiration rate fell, and the chest became clearer.

On October 10th the patient's voice became very hoarse, and he had attacks of acute dyspnoea. The air entry at the left base was poor. A week later he was slightly cyanosed, and had typical asthmatic attacks with prolonged expiration. Adrenaline and atropine gave some relief, but following the administration of half a grain of ephedrine twice a day by mouth the improvement was still greater, and the patient became less cyanosed. On October 26th his condition became worse, and he had marked difficulty with both inspiration and expiration. No drug seemed to give much relief. Next day he was worse, the difficulty being almost entirely inspiratory and laryngeal in type. Laryngoscopy showed the cords moving evenly and freely, with no oedema. Death took place on October 28th.

Post-mortem Examination.—The body was that of a well-built man of middle age. Nothing abnormal was found in the abdomen. The larynx, trachea, heart, and lungs were removed *en bloc*. The larynx was normal, and there was no oedema of the cords. The trachea was normal until within 2.5 cm. above the bifurcation, where a rounded bleb of mucous membrane 0.5 cm. in diameter projected into the passage. On opening this bleb it was found to communicate with a small hole 2 mm. in diameter between two rings of the trachea. The lungs showed small healed scars at the apices, otherwise they were normal. The heart muscle was well developed, of normal colour throughout, and there was no valvular disease. The aorta showed marked atheroma of the ascending portion and of the arch, but the descending aorta was quite clear. On the posterior wall of the first part were three holes, the smallest about 1.5 cm. above the valves and 0.5 cm. in diameter, and the largest 4 cm. above the valves and 0.75 cm. in diameter. The third was between these two. The two smaller openings were only a few millimetres deep, but on opening the largest a cavity about 5 cm. by 3 cm. was revealed. The main part of this cavity was slightly to the left of the mid-line, and it was continuous with the hole in the trachea. Its walls were thickened and covered with old blood clot. Within this was more recent clot.

Reviewing the history in the light of these findings, it appears probable that the coughing with the bronchitis caused the aneurysm to increase in size and to press on the anterior pulmonary plexus, particularly the left. This produced bronchial spasm, simulating asthma, which was partially relieved by atropine, adrenaline, and ephedrine. Then further increase in size took place and relief was not obtained. Finally rupture through the wall of the trachea occurred, with consequent obstruction and asphyxiation.

L. G. HILL, M.B., Ch.M.,
London, S.W.12. Late Assistant Medical Officer, West Middlesex Hospital.

Reports of Societies.

WORK OF THE ROTUNDA HOSPITAL.

A MEETING of the Section of Obstetrics of the Royal Academy of Medicine in Ireland was held on May 2nd, with the president, Professor A. H. DAVIDSON, in the chair. Dr. BETHEL SOLOMONS, Master of the Rotunda Lying-in Hospital, read the clinical report of this institution for the year 1928–29.

Dr. Bethel Solomons stated that 2,382 women had been admitted to the hospital, of whom 2,034 were delivered: 1,805 women had been confined in the extern department, and 2 had died. There had been 10 deaths in the intern maternity, so that altogether, in 3,839 cases, the mortality percentage was 0.31. The morbidity rate was the lowest in the history of the hospital, and, according to the British Medical Association standard, was 2.8 per cent.; the chance of sustaining such an extremely low level was slight, for complicated cases were continually being admitted from all parts of the country. Dr. Solomons commented on the difficulty in persuading women to attend the pre-natal department; he suggested that it might be necessary to withdraw maternity benefit, or to try some other drastic procedure, in order to persuade women that pre-natal care might save them from serious illness. The medical practitioners of the city should meet, with a view to starting propaganda, or to persuade the Government or the city authorities to act. It was noteworthy that in the majority of the serious cases dealt with in the Rotunda there had been no pre-natal care. The various statistics were considered. Although there were 9 cases of eclampsia with only 1 death, Dr. Solomons stressed the point that statistics of eclampsia in the present day could not be compared with those of the past, for most of the severe

eclampsisms nowadays would have been eclamptics. There were 554 cases of albuminuria in the hospital during the year. No death had occurred from placenta praevia, but 2 in 43 cases of accidental haemorrhage proved fatal. The lower segment Caesarean section was the favoured route; 3 cases of vaginal delivery after previous section were reported. In 34 Caesarean sections there was no mortality. Underpinning of the cord controlled haemorrhage on three occasions. Notes of the cases in the paediatric ward, and of the pathological and x-ray departments, were read. On the gynaecological side of the hospital, 654 operations had been performed, of which 105 had been for sterility. The speaker expressed his belief in the value of trachelorrhaphy and partial amputation of the cervix; when properly conducted good results ensued, and there was no trouble about conception, pregnancy, or labour. He had had to remove the cervix on four occasions where posterior division of the cervix had been performed elsewhere; this operation was a more frequent cause of sterility than a cure for it.

The PRESIDENT said that during the year under review the morbidity in the Rotunda Hospital had been brought to a level which had never been reached before, and the mortality also was extremely low. He thought some other method of treating cases of placenta praevia should be tried, since, although the maternal result was good, the infant mortality was very high. The fact that only one puerperal intrauterine douche had been given in the year was very satisfactory; the reduction in the morbidity rate seemed to indicate that in previous years too many intrauterine douches had been used. He thought that in many cases erosions could be treated palliatively, and it seemed to him a bad thing to amputate a cervix if the patient could be cured by any other means. He believed that amputation of the cervix must do harm, and often interfered with the normal course of labour afterwards.

Dr. GIBBON FITZGIBBON expressed satisfaction that conservative treatment was still being continued in cases of accidental haemorrhage, and that plugging had not been adopted. He did not think that patients could be classified into cases of toxaemic haemorrhage and cases of true haemorrhage merely by the presence of albuminuria, since some albuminuric patients would have a true accidental haemorrhage which would not be of a toxaemic nature. In the cases of accidental haemorrhage only six patients were primiparae: this fact, he thought, supported his view that accidental haemorrhage was often due to nephritis. Only two of the six primiparae could really be classed as cases of accidental haemorrhage. He felt that the time had come when it might be stated in the report that plugging was not indicated as a treatment in accidental haemorrhage, and preferably should be excluded. The use of quinine and oil for inducing labour was quite safe, but once labour had started the administration should be stopped and pituitrin be given. The use of quinine and oil for stimulating activity was excellent, but not for increasing activity. He thought tube induction was more physiological in its action than the use of bougies. Rupture of the membranes for induction of labour was excellent if used in the right type of case.

Dr. D. G. MADILL said the percentage of albuminuria was high, but these were cases which had not been seen before labour; this showed the importance of trying to persuade patients to attend out-patient departments. The morbidity rate for the year was one which had never before been touched. He thought subtotal hysterectomy was better than hysterectomy, and said he was not in favour of complete hysterectomy if it was possible to remedy the cervix from below, and then perform a subtotal hysterectomy. Dr. T. M. HEALY referred to the fact that Dr. Solomons had praised the use of saline in cases of accidental haemorrhage, but had said no deaths should occur. He personally thought that, in hospital, cases would always occur in which no resuscitation methods would be of value. He thought Dr. Solomons was particularly to be congratulated on the morbidity rate, and the low mortality in cases of section. The results in placenta praevia were, he thought, extraordinarily good. Dr. J. S. QUIN considered that cases in which inertia occurred late in labour with the head on the perineum could hardly be classified as true inertia. He thought that if the maternity benefit given by insurance companies was increased by 5s. to patients who attended pre-natal dispensaries, it would encourage patients to come for treatment, and would save the insurance companies by diminishing the number of cases of preventable illness.

Dr. R. TOTTENHAM asked if the treatment for eclampsia in the Rotunda Hospital was still that which had been employed by Dr. Tweedy, or if it had been modified in any way. He thought statistics were kept more carefully in the Rotunda Hospital than in most places outside Dublin. He asked if pelvic measurements were taken, and, if so, if much reliance was placed on them. Professor D. V. MORRIS said that the question of the toxaemias associated with nephritic lesions in pregnancy was of very vital importance. He would welcome the appearance of some propaganda which would enable doctors to bring directly to those concerned the dangers which women ran by negligence in these matters.

Dr. KERRY REDDIN had found that many patients were afraid to go to hospital out-patient departments because they did not like being examined by large classes of students. He thought some simple propaganda in the way of papers which could be easily read by these patients would be helpful. Dr. R. M. CORBET, referring to cases of ruptured uterus, said he thought the question was not one of plugging or operation, but of when the diagnosis of rupture was reached. If the diagnosis was made when the patient was undelivered, he thought laparotomy was required. In a great many cases, however, this was not possible, as the diagnosis was only made after the patient was delivered, and then the obvious thing to do was to plug the rent. In a number of these cases the plug did not stop the bleeding, because it was already stopped by the contraction of the uterine muscle; in cases where the bleeding continued the vessels were torn outside the uterine muscle, and therefore plugging would not stop the bleeding.

Dr. SOLOMONS, in reply, said he believed in Caesarean section for the primigravida with a central placenta praevia, provided that the patient was near to term; the same applied to the multipara, where there had been but little manipulation. He had given up plugging the vagina for accidental haemorrhage. He divided accidental haemorrhage into the true or traumatic, and the toxaemic; the latter was always accompanied by albuminuria and other toxaemic symptoms. He regarded the submammary method as the best for giving saline injections. In performing version for placenta praevia he preferred the combined method rather than trying external version first. He had found great difficulty each year in classifying certain cases as eclamptic or not. He had had no trouble with the oil-quinine method of inducing labour. Uterine inertia was always the bane of the obstetrician. Morphine was given as a routine in this class of case, and oxytocic drugs were only occasionally used. Intrathecal stovaine had a very small field of usefulness. He dissociated himself entirely from the Delmas procedure. Nowadays he classified as disproportion any case where there was a misfit between infant and pelvis; he still used the Skutsch pelvimeter, or x-ray pelvimetry if it seemed that the knowledge thus acquired could be of assistance. In ordinary rupture of the uterus plugging the rent was satisfactory in some cases, but the patient must be watched for different signs of internal haemorrhage, when laparotomy must be performed; in other cases immediate hysterectomy was necessary. Dr. Solomons based his opinion as to cancer following erosion of the cervix on his own experience, on the excellent work of Bailey, and on the opinion of various gynaecologists in different parts of the world.

THE TOXAEMIAS OF PREGNANCY.

AT a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, on May 16th, with the president, Dr. ARTHUR GILES, in the chair, Dr. G. W. THEOBALD read a paper which suggested a new conception of the toxaemias of pregnancy.

Dr. Theobald submitted evidence that eclampsia could neither be attributed to a placental toxin nor to any functional or organic renal defects. He claimed that the albuminuria so often associated with pregnancy and labour

was caused by pressure or traction affecting one or both renal veins. He believed that the toxaemias were originated by toxins absorbed from the intestinal canal and prevented from detoxication by a breakdown in the defences of the body. The toxins absorbed were in excess of the normal because of the intestinal stasis brought about by the bulk of the uterus. Uterine enlargement prevented also the proper absorption and assimilation of food and of those substances needed by the liver for the defence of the body. The liver had to function not only for the mother, but also for the foetus. There was considerable evidence that the ionized calcium in the blood was the most important element used by the liver in its detoxicating functions. The foetus required large supplies of calcium during the last four months of pregnancy; its requirements, combined with the other demands for this element, resulted in diminution of calcium in the blood, and allowed the liver to become damaged. There was interference with the metabolism of meat if the liver was injured, and thus there was an increase of guanidine, which was an antagonist of calcium and lowered the blood sugar figure. The toxaemias of pregnancy were, in fact, merely different expressions of a damaged liver. Dr. Theobald then summarized various experiments on dogs; feeding them on a lean meat and water diet had caused parenchymatous degeneration of the kidneys, especially affecting the convoluted tubules. In the liver there was severe degeneration of all types, including recent and hyaline thrombi of the veins and capillaries, cellular necrosis, and haemorrhage in the periphery of the tubules. These changes occurred more rapidly if pregnancy was present. Such dieting, moreover, brought about foetal death if it was started at the beginning of pregnancy, and Dr. Theobald suggested that human abortion might be similarly referable to incomplete diet. It was necessary, therefore, to ensure that the food of a pregnant woman contained a relatively low protein content, but was rich in calcium, iron, and iodine, and was well supplied with vitamins. It was also necessary to prevent intestinal stasis, preferably by suitable diet, but also, when required, by the administration of liquid paraffin.

Endometrioma.

Dr. F. J. HECTOR read a short communication on a case of endometrioma, which occurred in an unmarried woman aged 26.

In September, 1921, she had complained of dysmenorrhoea, and the uterus was found to be fixed in a retroverted position. At an operation adhesions were found, especially on the left side; left salpingo-oöphorectomy was performed with ventrofixation. In the next year subtotal hysterectomy became necessary; there was a hard mass in the base of the left broad ligament, in which the left ureter was found to be kinked and occluded. The left kidney was cystic, and the uterus showed a condition of polypoid endometritis. In November, 1926, a polypus as large as an almond was removed from the left vaginal vault. In June, 1929, fleshy polypi were excised from the cervix and the left vaginal vault; they consisted of endometrial tissue embedded in a fibrous stroma. In January, 1930, the patient complained of irregular vaginal haemorrhage, with pain in the left thigh and on micturition. An indurated plaque was felt in the left vaginal fornix, and radium treatment had been recommended.

PELLAGRA.

At the meeting of the Royal Society of Tropical Medicine and Hygiene, on May 15th, with Dr. G. CARMICHAEL LOW in the chair, two papers were presented on pellagra.

Dr. HORACE M. SHELLEY reported some observations he had made on this infection in Nyasaland, where it was endemic, particularly in the central prison at Zomba; cases also occurred, though less frequently, at the central lunatic asylum, and the disease was found sporadically over practically the whole country. The difference in incidence between the prison and the asylum was possibly explained by the fact that in the former institution as many as ten or twelve inmates shared one cell, whereas in the asylum usually not more than one or two individuals occupied one compartment. Diet did not appear to be of any great etiological importance, and the possibility of the cause being a microbic infection or an intoxication still remained. The supporters of the theory that the condition was due to a diet which lacked certain vital principles such as vitamin B 2, the pellagra-preventing factor, had been constantly changing their view as to which particular principle, by being absent from the diet, produced the disease. The characteristic erythema was probably trophic in origin. It had a potential maximum distribution, the exact extent of the area involved depending upon the amount of irritation to which it was subjected. The disease could be conveniently divided into acute pellagra, which was fatal in a few days, and chronic pellagra, characterized by repeated exacerbations. Types of the chronic disease were the subthyroid, the gastro-intestinal, the paralytic, and the mental; patients belonging to the last group suffered from delusional or manic-depressive insanity, and occasionally from acute mania. There was no definitely specific treatment, but the administration of thyroid gland tablets was of great benefit in certain cases, and should be tried as a routine measure.

Dr. WILLIAM SUSMAN followed with an account of the morbid anatomy and histology of pellagra. His investigation was based on six cases, of which two were of the subacute variety and four were chronic. The thyroid gland was found to be abnormal in every case, and in only one was the characteristic proliferation, pigmentation, and fibrosis absent. In all cases the thyroid lesion was without doubt the oldest, but in none was there sufficient evidence to warrant a conclusion that the process was an inflammatory one of the ordinary type. It was quite evident that the thyroid lesion was the primary one, and it was justifiable to suppose that the thyroid disorganized the action of the adrenal, and, in time, the action of the liver and pancreatic islets. As regards the etiology, the experimental injection of a minute anaerobic organism which he had isolated from the blood of several pellagrins had produced lesions in rats similar to those in the human subject. The lesions did not suggest the presence of a virulent organism; a toxin was more likely, but this might be the product of some organism. The thyroid function could, however, be disturbed by various causes, although he doubted whether dietetic influences alone could produce such profound changes as seen in pellagrins. However, if to a dietetic factor was added the action of an organism, possibly a fairly common organism, the possibility was much strengthened.

In the course of discussion, Dr. H. S. STANNUS suggested that the term "deficiency disease" for pellagra was but a half-truth; the condition might rather be a sort of intoxication due to an ill-balanced diet. Dr. W. R. AYKROYD said that it should never be forgotten that pellagra was, in 95 per cent. of the cases, a maize-eater's disease. Maize contained but little vitamin B 2, but not less than some other staple foodstuffs. He agreed with Dr. Stannus that lack of balance in the food might possibly be an explanation of this interesting disease. Dr. G. W. M. FINDLAY pointed out that a considerable number of epidemics of pellagra had been definitely cleared up by changes in diet—for example, among Armenian refugees, among Turkish prisoners of war in Cairo, and more recently in the Ukraine. The alterations observed in the thyroid gland might also be due to dietetic changes. Dr. J. BARCROFT ANDERSON suggested that it was not maize with the germ which was at fault, but maize deprived of the germ, which possibly contained a toxin which ordinarily the germ neutralized. Dr. P. H. MANSON-BAHR referred to outbreaks which occurred among prisoners of war. He had always been struck by the clinical resemblance of symptoms of pellagra to those of glandular deficiency. He also pointed out the fallacy underlying many early returns of pellagra. If the statistics relating to prisoners of war were taken, it would appear that pellagra suddenly broke out in epidemic form about 1918, but that was not really the case, for the disease existed before that, and was generally diagnosed under the name of some cutaneous malady.

Dr. SHELLEY, in the course of his reply, pointed out that pellagra occurred even when no maize was eaten. The Lancashire County Asylum at Winwick had 23 cases of pellagra in 1918. The patients showed all the typical lesions, including the dermatitis, and the outbreak came at a time when the asylum inmates were better fed, clothed, and housed than ever before.

UTERINE HAEMORRHAGE WITH OVARIAN HYPERTROPHY.

AT a meeting of the North of England Obstetrical and Gynaecological Society on April 11th, with the president, Mr. J. W. BURNS, in the chair, Mr. ALFRED GOUGH (Leeds) described two cases of excessive uterine haemorrhage associated with enlarged ovaries in young women.

Mr. Gough said that in one case the patient, aged 22, had suffered from menorrhagia and metrorrhagia for two years; the haemorrhage continued in spite of curetting. An operation was performed in which the right ovary was removed and half of the left was resected, the excessive loss of blood had been improved. In the other case the patient, aged 23, gave an identical history, though the losses had only been excessive for seven months. In each instance the removed ovary was between three and four times the normal weight; the organ was of a succulent consistence, showing histologically increase of the stroma with numerous small cysts. Mr. Gough said there were few references to this condition, which he considered was rare, but similar observations had been made by Blair Bell, Whitehouse, Wilfred Shaw, Cotte, and Fekete.

Mr. ERIC STACEY (Sheffield) thought this condition of hypertrophy of the ovary with cystic formation associated with excessive losses in young women was very common indeed; he had operated on many cases in which by partial resection he had reduced the bulk of the ovaries, and cured the patient. In his opinion the condition was associated with most of the causes of pelvic congestion, whether physical or psychological. Mr. A. A. GEMMELL (Liverpool) thought this was true of some cases, but that many young women suffered from menorrhagia, in which the cause was excessive function of the thyroid; these would be cured by x-ray applications to that organ. Others, however, had similar symptoms due to hypothyroidism, and were improved by daily thyroid therapy for some months. Dr. HUNTER (Manchester) considered that the giving of calcium chloride intravenously, with the addition of parathyroid extract, would generally prevent operation in these cases.

Spinal Anaesthesia in Midwifery.

Dr. HUNTER (Manchester) read a short note on the value of spinal anaesthesia in cases of difficult midwifery. He thought the scope of its use was limited, but one advantage was the greater relaxation of the birth passage without interference with the uterine contractions; chest complications seemed to be fewer, and there was easier breathing than under general anaesthesia, which facilitated the operative manœuvre. In fact, its greatest advantage was that with spinal anaesthesia the prognosis was better in cases where an otherwise healthy patient had had a temporary acute anaesthetic bronchitis, as a result of one or several previous and badly administered anaesthetics. He advocated it, therefore, in cases of failed forceps, and quoted two cases. He had employed it in three cases in which a dry, prolonged labour, with a rigid, undilated cervix, had terminated in delivery completed by cervical hysterotomy and the application of forceps. He had also used it in cases of heart disease.

Dr. BURNS read a similar communication on the value of spinal anaesthesia in cases of Caesarean section; he considered that its scope in midwifery was limited to this operation. He had found that its use led to a diminution in the amount of blood lost, with no increased risk to the mother and child, and a more speedy recovery of the patient, without chest complications.

Congenital Recto-vulval Fistula.

Dr. A. M. CLAYE (Leeds) described a case of congenital recto-vulval fistula, in which multiple fibroids, impacted in the pelvis, obstructed the progress of a full-time labour. The patient's menstrual history had been normal, and there had been no discomfort during gestation. Dr. Claye had delivered her by Caesarean section, followed by subtotal hysterectomy; a living child had been born, and both it and the mother had done well. He had found in the literature two cases only in which a patient had become pregnant with this abnormality. Dr. BURNS said that in 1929 he had reported a similar case; the patient, who had had three children, was unaware of the presence of this abnormality. Mr. W. GOUGH (Leeds) added that he had seen a similar case.

THE PHYSICAL AND MENTAL ASPECTS OF THE JEW.

THE Jewish Health Organization of Great Britain held a "symposium" on May 25th, at the Conway Hall, Red Lion Square, when the subject was the physical and mental aspects of the Jew. Sir HUMPHRY ROLLESTON, who presided over an audience so large that an adjournment had to be made to a larger hall, said that the discussion must be of wide interest because it dealt with a race of extraordinary intellectual ability, which had attained unrivalled success in art and science, in culture, and also in finance. One interesting point was that the Jewish race had retained in a most marked degree certain physical and mental characteristics.

Professor M. GINSBERG, dealing with racial characteristics, said that special difficulties as regards Jewish anthropology were race prejudice, the complexity of the facts, and comparative ignorance of the laws of heredity. Prejudice showed itself in two ways. On the one hand, there were Jews who, in order to substantiate their general belief in the importance of assimilation, tried to make out that there was no such thing as a Jewish race; hence they stressed the approximation of physical characteristics of the Jews to those of the peoples among whom they lived. On the other hand, there was prejudice, from the point of view of ardent Jewish nationalists, who maintained that the Jewish race was pure. Neither of these positions could be maintained. Professor Ginsberg confined himself to some remarks on stature, head form, pigmentation, and nose form. He had collated such information as existed with regard to the stature of Jews in different parts of the world; the mean stature appeared to be 162 cm., which was slightly less than the average. There were, however, certain approximations between the stature of Jews and that of their hosts. It was generally recognized that stature was in the main determined by heredity, but undoubtedly it was also capable of being affected by environmental changes. It was conceivable that the low stature found in Poland and Russia was not a racial trait, but was due to the conditions under which the people lived. Most Jews in different parts of the world were undoubtedly broad-headed, though not to such a degree as the Caucasians or the Armenians. In this respect also there was an approximation to the peoples among whom they lived. The hooked nose was not really common among Jews; it was only found in about 14 per cent. of the Jews in Poland, and in other countries to an even smaller extent. It was probably much more common among Armenians and the Alpine populations of Central Europe.

Dr. L. ISSERLIS of the London School of Hygiene and Tropical Medicine presented some Jewish vital statistics. The Jewish population of the world, he said, so far as could be computed, constituted 0.75 per cent. of the total population. By a numerical accident, this represented almost exactly the proportion of Jews to the population of Great Britain. For Europe as a whole the figure was 2 per cent. If some figures relating to the Jewish population fifty years ago were to be accepted, the annual rate of increase in the Jewish population during the last half-century had averaged 1.8 per cent. on the population for the preceding year. He was unwilling, however, to accept these figures, though he believed that the Jews had increased markedly at a greater rate than the rest of the population. Time and place appeared to have parallel effects on the Jewish and non-Jewish sex and age ratios.

Dr. W. M. FELDMAN dealt with the question whether there were any theoretical grounds for expecting diseases to have a different incidence or mortality rate or to run a different course among Jews. He reminded the audience of certain fallacies which must be guarded against; it was wrong, for example, to assign a racial reason for any observed differences until all environmental factors had been exhausted. With regard to infectious diseases, Jews availed themselves of preventive measures and sought medical advice sooner than did Gentiles. There were from 25 to 50 per cent. more deaf-mutes among Jews than among Gentiles, possibly owing to the fact that consanguineous marriages were three times as common in Jewry. The most common single cause of blindness was ophthalmia neonatorum; this was certainly not more frequent among

Jews, but myopia was commoner, and since diabetes occurred more often in Jews it was reasonable to suppose that the incidence in them of diabetic glaucoma was greater, but this view was not accepted by all observers. Syphilis was not very common among Jews, and alcoholism, with the diseases caused by it, was conspicuous by its absence. Arterio-sclerosis was probably more common, on account of the greater pace at which Jews lived, as well as their liability to greater mental strain. Retinitis pigmentosa was said to be frequent, and at one time was regarded as exclusive to Jews. The alleged greater frequency of haemophilia among Jews might be more apparent than real, since the condition was more likely to be detected among the children at circumcision. Cancer, taking the condition as affecting all organs, was neither more nor less common than among Gentiles of the same age distribution. Uterine cancer, however, was certainly less often met with, and mammary cancer was very rare. On the other hand, gastro-intestinal cancer was perhaps more frequent. Dr. Feldman believed that cancer of the uterus and of the breast was a protest by those organs against being thwarted in their natural physiological functions, as a result, sometimes, of the practice of contraception or of absence of breast-feeding. Of the metabolic disorders, there was no doubt that diabetes was found often among Jews; in his private practice, mainly Jewish, he encountered this condition at frequent intervals; in his hospital practice, mainly Gentile, it was much more rare. The disease was, however, less severe in Jews, owing to their habit of seeking medical advice early.

Dr. E. MILLER discussed the Jewish mind in health and disease. Some investigators in the field of psychology, he said, had gone so far as to declare that the Jewish people had a specific temperamental quality. There was this to be said, that the Jew thought verbally, and the non-Jew pictorially. In the case of Jewish children verbal expression and imitation of the linguistic habits of the adult seemed to come more easily and earlier. Musical ability was also pronounced among Jews, perhaps because music was allied to the world of enumeration and mathematics, in which they also excelled. As regards mental disorders, Jews were prone to suffer from pure hysteria and anxiety hysteria, but psychasthenia and other forms of introversion were very rarely met with. For every twenty cases of hysteria in one form or another he encountered not more than two or three of psychasthenia. He had noticed the frequency of metabolic disturbances associated with psychoneurosis in Jewish patients. As to varieties of insanity, when Jews suffered from manic-depressive insanity the depressive phase dominated the picture. In dementia praecox there was no special characteristic in Jewish patients except the absence, or relative absence, of mystical ideas from their hallucinations. He felt that the history and vicissitudes of the people must have told on the Jewish constitution, but at the same time he failed to find marked evidence of a tendency to neurosis. Among 3,000 cases of war neurosis he came upon actually only seven among Jews.

Dr. D. N. NABARRO said that he did not think the actual make-up of the Jew, apart from the nervous system, differed from the make-up of any other race, but possibly the anatomical make-up of the nervous system might have something to do with the production or causation of certain diseases, such as diabetes and the various neuroses to which Dr. Miller had referred.

In the course of some further questions and discussion, Dr. ADOLPHE ABRAHAMS remarked that what struck any observer of the Jew was his extraordinary adaptability; if he happened to live in a country which had certain diseases peculiar to itself, he forthwith adapted himself to those diseases. But there were some diseases which, if not restricted to Jews, were found much more frequently among them, and these were often unusual and rarely seen conditions. If a medical man put together the diseases he could not diagnose, he would find a greater percentage of them in Jews than in non-Jews. Diseases extraordinarily common among Jews were those of the sympathetic nervous system. Disturbance of the endocrines was frequent, especially in Jewesses, and conditions like urticaria, asthma, and so on, were often encountered.

Reviews.

CLINICAL ASPECTS OF CHEMICAL PATHOLOGY.

DR. G. A. HARRISON'S *Chemical Methods in Clinical Medicine*[1] is in some ways a unique work. There are a good many textbooks of biochemistry; even more which deal with practical physiological chemistry; but Dr. Harrison has contrived to take something from each side of the subject, and to weld the parts into a coherent and most interesting whole. It is clear that he draws from a wide practical experience; any laboratory worker will at once recognize the "snags" he describes as old acquaintances, and his methods of circumventing them as sound and practical.

So far as technical methods are concerned, the book is a fairly complete laboratory manual for the chemical pathologist. All the routine methods he is likely to require are described, and in addition, there are to be found directions for dealing with many of the odd things that turn up unexpectedly, and which, while too rare to be regarded as matters of routine, may easily prove baffling and troublesome to one who feels that he is expected to provide information for a clinical staff whose ideas about his problems, methods, and difficulties are rather hazy. For example, the occurrence of Bence-Jones protein in the urine is very rare, and the pathology of the condition is so obscure that it has little theoretical importance. On both counts a chemical pathologist might be excused for missing it; yet if he did so he would certainly be inclined to criticize himself. Dr. Harrison not only describes the usual tests for the substance, but points out their difficulties, why the substance may be overlooked, and the precise precautions to take to avoid such a happening. Blended with the exposition of practical matters there is some very sound discussion of the theoretical aspect of the subject. The author goes pretty fully into the theoretical basis of the various tests, and points out their limitations. He rightly lays great emphasis on the fact that the findings of the chemical pathologist can be used to full advantage only when viewed beside those of the clinician, and we feel sure that he also implies that the former should be taken fully into the clinician's confidence. The book should be of great use to three classes of people: first, to the chemical pathologist; secondly, to the clinician who wishes to get the full value out of laboratory tests, and, incidentally, to understand something of his colleague's problems and difficulties; and thirdly, to the senior student or to the houseman working for one of the higher degrees. It is becoming increasingly important for candidates that they should have an intelligent interest in laboratory methods, and be themselves able to undertake the simpler manipulations entailed; this book should help them considerably in these directions.

That a fuller understanding and a better co-operation between clinician and pathologist is desirable has long been plain. At present much effort is wasted in performing tests whose results are not properly interpreted, and it sometimes happens that the pathologist is set impossible tasks simply because the clinician has inadequate knowledge of the possibilities and limitations of pathological technique. Dr. Harrison's book should be studied by both parties.

JAUNDICE.

IN the Syndromes of Jaundice[2] Dr. P.-A. CARRIÉ of Paris, while showing how much the French school has done in unravelling the knotty problems of this subject, is broad-minded in his appreciation of the work done by authors of other nationalities, German and English speaking. He pays a high compliment to the work of Dr. A. R. Rich of Baltimore, and gives not only full credit but a superfluous accent to Dr. J. W. McNée. Although in recent years

[1] *Chemical Methods in Clinical Medicine.* By G. A. Harrison, M.D., B.Ch.Cantab., etc. Churchill's Empire Series. London: J. and A. Churchill. 1930. (6 × 10, pp. vii + 534; 64 figures. 18s.)

[2] *Les syndromes ictériques.* Par P.-A. Carrié, Médecin des Hôpitaux de Paris. Bibliothèque des Grands Syndromes. Paris: G. Doin et Cie. 1930. (6¼ × 9½, pp. 452. 85 fr.)

the theory of jaundice has undergone most radical changes, Dr. Carrié dutifully and gracefully stands up for the men of old time, and shows that many of the modern conceptions are in reality old. Thus in 1857 Gubler considered that in haemolytic jaundice a pigment—haemaphein—other than, though allied to, bilirubin was formed; and in this century Hijmans van den Bergh has shown the difference between the blood bilirubin in obstructive and that in haemolytic jaundice. After a full discussion of the site of manufacture of bilirubin, in which the experiments of F. C. Mann of the Mayo Clinic and their repetition with a divergent deduction therefrom by Melchior, Rosenthal, and Licht are considered, the question whether or not the liver cells play any part other than excretory in the formation of bile is left open. In like manner the origin of the bile acids, cholesterol, and urobilin is dealt with in separate sections.

The forms or syndromes of jaundice described are the mechanical or obstructive, infective, toxic, jaundice in certain hepatic and biliary diseases, such as gall-stones, cholangitis, and cirrhosis; the haemolytic form, familial cholaemia, and jaundice in the newly born. Familial cholaemia (described by Gilbert, who thought it was due to chronic inflammation of the intrahepatic bile ducts caused by intestinal infection) has attracted little attention since familial haemolytic jaundice has become generally recognized. Dr. Carrié, however, fully accepts it as distinct from familial haemolytic jaundice, though he states that it is rare, if not exceptional, and ascribes it to congenital insufficiency of the hepatic cells and not to intrahepatic cholangitis. The fragility and other changes of the red cells characteristic of familial haemolytic jaundice are absent in familial cholaemia, and thus justify the view that the two are two separate conditions.

Clearly written, this monograph provides a good account of the problems of jaundice.

CLINICAL OPHTHALMOLOGY.

THERE are many excellent textbooks and handbooks of the diseases of the eye. Commonly these begin as the personal record of some diligent investigator, but for the most part the very success of such a work determines the impersonal character of the book, and there is a tendency to suppress personal opinion and observation in favour of a more averaged or generalized statement. This becomes increasingly evident with each successive edition of a popular work. The standard representation of the clinical characters of any set of bodily diseases leaves room for the occasional presentation of a more personal outlook. A little book of this order is that on the *Affections of the Eye in General Practice*,[1] by Mr. R. LINDSAY REA. In the space of some 150 pages the author contrives to give a lively and satisfactory presentation of some of the commoner diseases of the eye, freely illuminated by references to personal experiences. Quite the most interesting of the chapters is that on the hygiene of the eyes; in this the author ranges in a few pages over the whole of a life, from the pre-natal state to senility. There is a note on the growth of the eyes of the unborn child and the possibility of their being injured by maternal disease or interference with the progress of the gestation. Thence the author touches on the risks of birth, the trials of infancy, the propriety of school work, and the necessity for the periodic examination of the eyes during school life. Note is made of the risks of industry and their prevention, the causes of fatigue in student life, the onset of presbyopia, and the degenerative changes of age. Mr. Lindsay Rea maintains that the cinemas cannot be blamed for producing defects of eyesight; they are rather to be praised for revealing them; a large proportion of children admit that they cannot read the subtitles on the screen as well as their parents and others can. No one should be permitted to sit close to the screen, because there the flicker is observed at its worst, and this produces extreme fatigue of the eyes. The book is well illustrated with both black-and-white and coloured pictures, many of which have been drawn by the author.

[1] *Affections of the Eye in General Practice.* By R. Lindsay Rea, B.Sc., M.D., M.Ch., F.R.C.S. London: H. K. Lewis and Co., Ltd. 1930. (Demy 8vo, pp. xvi + 156; 33 figures, 7 plates. 10s. 6d. net.)

The usefulness of the *Manual of Diseases of the Eye*,[4] by MAY and WORTH, is evident from the fact that it has now attained a sixth edition, and of these editions many have been reprinted several times. The book is a good straightforward presentation of the facts of the diseases and disorders of the eye. It is tersely yet clearly written, and well illustrated. In this new edition the whole matter has been revised without making any radical change, except at one place. A new and short chapter on the slit-lamp and corneal microscope has been written by Mr. Harrison Butler, who in eight pages contrives to give a presentation of the basis of this most interesting form of investigation, which is calculated to grip the attention of the student. The book is certain to attract and satisfy many students and practitioners.

STROGANOFF'S TREATMENT OF ECLAMPSIA.

THE appearance in English of Professor STROGANOFF'S own account of his *Improved Prophylactic Method in the Treatment of Eclampsia*[5] will be welcomed by all who are engaged in the practice of midwifery, and we owe a debt to Dr. Haig Ferguson for having introduced this book to the English-speaking people.

After a preliminary survey of the various methods that have from time to time been used in the treatment of eclampsia, Professor Stroganoff gives a short outline of the history and progress of his own particular method, and then in a new section considers the pathogenesis of eclampsia so far as it has any bearing on the treatment which he adopts. Without entering on a long discussion as to the precise origin of the toxin, he assumes that eclampsia is due primarily to the circulation in the body of some *poison (probably of placental origin) which causes* vaso-constriction in the various organs—notably in the liver, kidneys, and brain. Added to this he postulates a greatly increased excitability of the nervous system, and in his view this is at least an equally important factor in bringing about the vaso-constriction. The lesions that are found post mortem in the kidney, liver, and brain he regards as secondary to the vaso-constriction, brought about by the circulating toxin and by the increased excitability of the nervous system. He points out that during and shortly after a fit asphyxia is a most important factor in causing further cellular injury—in this way eclampsia is looked upon as resulting in a vicious circle, each succeeding fit tending not only to weaken the patient, but predisposing to another. To break this vicious circle is the object of his treatment, and he believes this is best done by devoting attention to the hyperexcitability of the nervous system.

Professor Stroganoff's scheme of treatment is fully set out, and for this reason alone the book is valuable, since so much confusion has hitherto existed as to the precise details which he employs, and it has been his contention that the details are of the greatest importance. Broadly speaking his method consists of (1) removal of all irritation, (2) depressing the excitability of the nervous system with chloroform, morphine, and chloral, (3) assisted delivery in the second stage of labour whenever possible. He insists on the futility of hard-and-fast rules for the treatment of a disease where so great differences in severity and attendant circumstances are found, but nevertheless he attempts to give various "rules" for the treatment of milder cases. In very severe cases he is emphatic in his denial of any dogma, and is ready at all times to make use of auxiliary methods of treatment. Thus he finds room for venesection, and even, on rare occasions, for Caesarean section. Professor Stroganoff has found it impossible to prepare a fixed scheme for severe cases, and repeatedly points out that such cases must be treated not by rule, but on their merits.

A study of this book brings home to us, in a way that no summary is able, the importance of attention to detail in the "improved prophylactic method," and it shows that for its successful application the constant attention

[4] *A Manual of Diseases of the Eye.* By Charles H. May, M.D., and Claud Worth, F.R.C.S.Eng. Sixth edition. London: Baillière, Tindall and Cox. 1930. (5½ × 8, pp. viii + 475; 337 figures. 15s. net.)

[5] *The Improved Prophylactic Method in the Treatment of Eclampsia.* By Professor W. Stroganoff. Third edition, thoroughly revised and completed. First English edition. Edinburgh: E. and S. Livingstone. 1930. (Demy 8vo, pp. viii + 154. 10s. 6d. net.)

of the doctor is necessary. The "Stroganoff treatment" of eclampsia is a term that is used throughout the world, but this book—the first full account in English—will do much to dispel misconceptions about what this term implies. It is so well written, and so remarkably free from dogmatic statements, that it will almost certainly result in an increased application of Professor Stroganoff's principles among English-speaking obstetricians.

MALE SEXUAL DISORDERS.

SOMEWHERE on the border between uro-genital surgery, neurology, and psychopathology, and encroaching on all of them, is a region littered with disorders of the sexual function which have sometimes a psychological basis, sometimes an organic basis, sometimes both. It is a debatable ground which neither the urological surgeon, nor the neurologist, nor the psychopathologist has ventured to explore thoroughly, perhaps from fear of being regarded by the others as an intruder. Mr. KENNETH WALKER, being a urologist with psychological leanings, has taken the bold course of mapping out this region, and in *Male Disorders of Sex*[6] he presents his discoveries about primary and secondary impotence, homosexuality, masturbation, pollutions, coitus interruptus, priapism, continence, and sterility, to the non-expert practitioner and student. The word "discoveries" is used advisedly. Mr. Walker is intimately acquainted with the literature of what is called "sexology"; but the conclusions in the work under review are derived almost entirely from his own observations and experience.

The statement that the problems considered in this little book have been neglected because they overlap bordering specialties represents only part of the truth. The reason that would be favoured by many modern psychologists—namely, that the problems are neglected simply because they are sexual, and therefore subject to repression—is equally inadequate. Sexual problems which fall clearly within the province of the neurologist or the urological surgeon are given due weight both in the student's curriculum and in medical literature; those that fall within the province of the psycho-analyst stand in no serious danger of being overlooked. The real explanation, as Mr. Walker himself suggests, is that these borderline disorders of sex are regarded by most practitioners as being among the minor ailments. They do not kill, and only very rarely are they associated with killing diseases. It should be realized, however, that the doctor's estimate of what constitutes a minor malady and the patient's may differ considerably. In our medical schools students learn a great deal about, for example, appendicitis, and little or nothing about impotence. It is inevitable, therefore, that in the student's scale of values appendicitis should rank very high and impotence nowhere. But if a candid patient were asked which of these conditions he would rather suffer from there can be little doubt what his answer would be. The student is father of the practitioner, but the values he carries from hospital rarely survive the daily testing of general practice. The rare tumours and pretty cases, the gastrectomies and the Wertheims, recede in importance, and he has to face problems which in the course of his hospital training he might have been excused for believing to be non-existent. Among these problems those which form the subject of Mr. Walker's book will loom large or small in the practice according to the practitioner's own attitude towards them. Patients do not talk easily about disorders in their sexual life, even to the best-informed and most understanding physician. The physician who lacks the requisite sympathy and the knowledge may well conclude from the fact that none of his patients seem to mention them that these disorders are among the rarest that afflict mankind. From a study of *Male Disorders of Sex* at least these two truths emerge: that psychogenetic or quasi-psychogenetic disorders of sex cause a great amount of preventable suffering; and that their treatment presents problems which are as much worthy of the physician's attention as any of the problems of medicine.

[6] *Male Disorders of Sex.* By Kenneth M. Walker, F.R.C.S. London: J. Cape. 1930. (Cr. 8vo, pp. 121; 1 figure. 5s. net.)

In writing a small book on a large subject the author must of necessity limit his field, and Mr. Walker has wisely chosen the strictly practical problems involved in the diagnosis and treatment of the most common disorders of sexual function. Thus he devotes four chapters to impotence, two chapters to sterility, and one each to homosexuality, masturbation, pollutions, priapism, and continence, but only a few words incidentally to sadism and masochism, which, as fully developed clinical entities, come more within the province of the alienist than of the general physician. Throughout the book, moreover, he writes with wisdom and candour about everyday sexual problems—for example, abstinence, promiscuity, sexual excess, homosexuality—which are at least as much the concern of the moral philosopher and the sociologist as they are of the physician. In his observations on these matters he will satisfy neither those who by temperament object to any discussion on sexual problems at all, nor the growing number of persons who are so busy in discussing sex frankly that they can have but little time left for anything else. He takes not so much a *via media* between extreme emotional attitudes as an entirely new way in which the end is reached by the difficult and relatively unpopular expedient of clear thinking. The style of the book is admirable: clear and unobtrusively epigrammatic.

CLASSIFICATION OF BACTERIA.

FOR many years there has been felt a need for a standard classification of bacteria, and the third edition of *Bergey's Manual of Determinative Bacteriology*[7] continues a work which meets this need very satisfactorily. The manual is prefaced by an account of the history of its subject, commencing at 1786 and closing with notes on the basis of classification which have been adopted by the Society of American Bacteriologists in 1919. It is on the system given by that body that Bergey's book is founded. In a code are laid down the points which should govern the nomenclature of organisms, and some recommendations for the avoidance of certain undesirable features in the naming of new bacteria. It is suggested that the manual may be used for the identification of organisms by reference to their morphology, cultural characters, and other diagnostic points, and the matter is arranged with this object in view.

One of the important changes in this edition is the separation of the typhoid and dysentery groups of bacilli; the latter come under the genus Shigella Castellani and Chalmers, and the former make the genus Eberthella. It is likely that other regroupings may be called for as work progresses, and the co-operation of bacteriologists in supplying further data is invited. In discussing the habitat of the *Alkaligenes abortus* (the some-time *Brucella abortus*) no mention is made of its causing disease in man, as has frequently been reported during recent years. The close resemblance to, and perhaps identity with, the *A. melitensis* is commented on. The subject-matter of such a book as this is ever on the increase, and in this edition over 200 additional organisms are described. The excellent index helps to make the manual an authoritative guide.

NOTES ON BOOKS.

THE enormous output of medical monographs, systems, handbooks, digests, treatises, and essays from the mid-European universities and hospitals of late years makes the task of the selective reviewer very hard. Off the well-known track is a series of monographs, edited by Professor Schwalbe, bearing the comprehensive title Diagnostic and Therapeutic Errors in General Medicine and How to Avoid Them. The volume devoted to metabolic disorders[8] is written by Professor S. ISAAC of the Jewish Hospital at Frankfort-on-the-Main. It conforms to the conventional type in being a paper-backed monograph of 150 pages, complete in itself, and well printed

[7] *Bergey's Manual of Determinative Bacteriology.* By David H. Bergey, assisted by a Committee of the Society of American Bacteriologists. Third edition. London: Baillière, Tindall and Cox. 1930. (6 × 9½, pp. xvii + 589. 27s. net.)

[8] *Diagnostische und therapeutische Irrtümer und deren Vermeidung, Innere Medizin. Erstes Heft: Krankheiten des Stoffwechsels.* Von Professor Dr. S. Isaac. Zweite, vollkommen neu bearbeitete Auflage. Leipzig: G. Thieme. 1929. (6½ × 9¾, pp. 150; 12 figures. M. 10.)

and indexed. With the reappearance of obesity and diabetes mellitus on a large scale in the richer parts of Central Europe, Professor Isaac has had large resources and material to draw upon, but though the bulk of the monograph is given over to diabetes mellitus it includes no information about this disorder that is not already accessible in works written in the English language. The diagnostic pitfalls in diabetes mellitus are laboriously and minutely explored along the familiar lines; the usual large and complicated dietetic tables, with a good deal derived from Noorden, appear in full. There is a bright little chapter on prophylaxis, with special reference to family incidence and the association between diabetes mellitus and other metabolic maladies, such as cholelithiasis, and the "prediabetic life" is briefly considered. The other sections of the book seem disproportionately short, but a concise and useful review of obesity is presented, and clear consideration is given to exogenous and endogenous fat disturbances. Most of the latter admit of endocrinopathic classification, and the author deals with the thyroid, gonads, and pituitary very fully, and with the pineal, thymus, and adrenal less fully. "Cerebral" adiposity is a new term, and is here given to that type of obesity well known in this country as a sequel to encephalitis lethargica. The other maladies discussed are gout, diabetes insipidus, and the rarer urinary excretion disorders.

A second edition of the small handbook entitled *Varicose Veins, Hæmorrhoids, Varicocele, Hydrocele, and their Treatment by Injection*,[9] by Dr. R. THORNHILL, has now appeared. The new matter includes a list of warnings at the end of each section against various dangerous proceedings and possible omissions in the investigation and treatment of a case.

Mr. R. A. FISHER'S *Statistical Methods for Research Workers*,[10] which is intended to be of assistance, especially to the biologist, in applying statistical tests to numerical data, was noticed in these columns on the appearance of a second edition. A third and revised edition has now been published, in which two sections have been added to the chapter on the principles of statistical estimation.

A description of present-day contraceptive technique appears in the revised and enlarged edition of *Parenthood: Design or Accident*[11] by MICHAEL FIELDING. The first edition was the subject of editorial comment in our issue of August 4th, 1923 (p. 218). The chapter on methods has been completely rewritten, and now includes discussions of the relative efficiency of the chief varieties of mechanical pessaries and of the effervescing and non-effervescing chemical pessaries. In a chapter on methods still under investigation the author deals with the production of revocable sterility by means of Gräfenberg's ring, *x* rays, and other physical agents, spermatoxins, and sex hormones. Two appendixes have been added, one on the work of the birth control clinics, the other giving the addresses of, and hours of attendance at, a number of birth control clinics throughout the country. The author is a medical man writing under a pseudonym.

Of the making of books on massage there is no end. The fifth edition of NISSEN'S *Practical Massage and Corrective Exercises*[12] is a reminder of this fact. Each excellent director of a school, be it Swedish or Japanese, feels it his duty to instruct the public, and does so. This book goes somewhat beyond mere massage, for the author discusses the pathology of some deformities in a controversial manner. Among other remedies for congestion of the brain "breech beating" is recommended. But in anæmia of the brain the case is altered: here we are to practise "back percussion." The distinction is a nice one, and we quote it as an indication of the fine discrimination of the author, and leave it at that.

In *Orthodontics*,[13] the subject of the twelfth volume of Outlines of Dental Science, Mr. A. G. WILSON gives in short compass a description of the devices and appliances used for guiding the normal development of teeth, arresting developmental abnormalities, and correcting malocclusion of the teeth and associated parts. The work, we think, might have been improved by the inclusion of a longer chapter on the etiology of malocclusion, for the recognition of the basic factor in nearly all cases of dental arch deformity—namely, failure of maxillary growth—must be of prime importance in indicating the lines of treatment. Mr. Wilson has written a valuable book on the mechanical aspects of orthodontics.

In view of the growing popularity of camping and caravanning nowadays a pamphlet by Mr. J. HARRIS STONE, entitled *Caravan and Camp Cooking Recipes*,[14] will doubtless be welcomed by many who seek improved health in the open air. Useful hints are given for the preparation of palatable meals as economically as possible.

PREPARATIONS AND APPLIANCES.

A RADIUM NEEDLE INTRODUCER.

MR. R. BROOKE, M.S., F.R.C.S. (Worthing), has designed an improved apparatus for inserting radium needles. He writes: The instrument consists of a hollow trocar (A) with a bevelled needle point, and slotted on its upper surface: in it passes a stylet (B C). A revolving cylinder, measuring 1⅝ inches in length, contains twelve chambers, each slotted on its outer surface and designed for the reception of the radium needles. Each chamber is loaded with a threaded needle before use; the threads are drawn out of the slots on the outer surface and passed beneath the small metal flange (D), which anchors them until they are required. The handle by which the instrument is held is indicated by (E).

The trocar is first introduced into the tissues with the stylet in position. When the required depth has been reached the stylet (B) is withdrawn. The catch (F) is a restraining catch, and prevents the stylet from being drawn out completely. The cylinder is then rotated until the first chamber comes into line

with the trocar; this point is automatically regulated by a ball catch (G). The stylet is next pushed home, and the threaded needle is forced through the trocar into the tissues, the thread lying in turn in the slot on the upper surface of the chamber and in the slot of the trocar. The stylet is then withdrawn, and the cylinder is again turned until the next chamber is engaged, when a second needle is introduced; or the trocar may first be withdrawn and re-introduced at a fresh spot.

The special value of this instrument lies in the fact that it saves the time wasted during the operation in the threading of needles and in their introduction with forceps by the surgeon into the trocar each time. The needles are all threaded by the sister before the operation, and the chambers are loaded. The appliance can be obtained from Messrs. Down Bros., Ltd., St. Thomas's Street, S.E.1.

POWDERED ERGOT IN CAPSULES.

Recent researches[1] carried out in the Pharmacological Laboratory of the Pharmaceutical Society have shown that the stability of liquid ergot preparations is very unsatisfactory, and that liquid extract of ergot, when made by a satisfactory process and stored in ice, lost half its pharmacological activity in ten weeks. On the other hand, it was shown that defatted powdered ergot was stable as regards its pharmacological activity. These results have led Messrs. Stafford Allen and Sons to put on the market, under the name "erbolin," a preparation of powdered ergot in capsules. The drug has been standardized biologically by the Pharmaceutical Society, and each capsule of erbolin contains the equivalent of 0.5 mg. of ergotoxine phosphate. This corresponds to the alkaloidal content of 1 c.cm. of fluid extract of ergot (*U.S.P.*) of full potency. The unreliability of the official preparations of ergot in this country has caused the drug to fall into disfavour, which probably is unmerited, and this simple preparation deserves a careful clinical trial.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

ANNUAL MEETING.

THE Prince of Wales, who presided over the annual meeting of the King Edward Hospital Fund for London at St. James's Palace on May 27th, read a message from the King expressing pleasure that, as a result of the Thank-offering Fund and of the gifts received from Sir Otto Beit and Mr. Roger Parr, the King's Fund possessed a large supply of radium for loan to hospitals within its area. This enabled a wider distribution to be made of the radium at the disposal of the National Radium Commission.

Before reviewing the principal items of the annual report for 1929, the Prince announced that, since the end of the year, the capital account had been augmented by a legacy of £90,000 from the late Lord Revelstoke, and that an anonymous donor had given £24,500 in the form of securities. The two outstanding events of the year, he said, were the Thank-offering Fund for the King's recovery and the purchase of radium for loan to hospitals. The sum received from the Thank-offering Fund was £257,000, which included the magnificent gift of £105,000 from "Audax." As an instance of the lasting effect of this example, an anonymous donor had recently offered to sign a seven-year agreement, on the same lines as "Audax," for £10,500. Great advance had been made during the last eighteen months in providing hospitals all over the country with radium. In addition to the supply of radium owned by individual hospitals, an amount valued at £350,000 would be controlled by the Fund and by the National Radium Commission. At the disposal of the Fund there was a quantity of 10 grams, which would be loaned to hospitals in London, while those outside London would be supplied by the National Radium Commission, which possessed an even larger amount. Both bodies had agreed to work in consultation when desirable, and their scientific records would be in the same form.

Referring to the establishment of the London Voluntary Hospitals Committee, appointed to co-operate with the London County Council, the Prince remarked that a really good hospital service must combine in due proportion the qualities of efficiency, flexibility, organization, and freedom. Its essence consisted in a number of individual doctors treating a number of individual patients—one of the most intimate personal and human relationships that existed outside family life. It must provide for the advance of medical science, and allow scope for both individual genius and organized team work. It was important that the spirit of the voluntary hospitals, to which £2,700,000 was contributed annually in London alone, should be preserved, and should continue to permeate the whole medical service.

Accounts for 1929.

The amount for distribution in 1929 was maintained at £250,000, made up of dividends and voluntary gifts. This sum, however, left nothing over for the special pensions grants, but a legacy of £29,000, received since the end of the year, will enable the Fund to pay these grants without affecting the ordinary distribution, and also to set aside a further sum to meet the additional liabilities undertaken by the Fund in promising the special grants for seven years. The actual liability in 1929 was £13,734. An increase has been made to the special pension reserve, bringing it up to £45,000. Included in the accounts is the first of the seven annual instalments of the gift of £105,000 from "Audax," and the gifts of £50,000 from Sir Otto Beit and £10,000 from Mr. Roger Parr, for the purchase of radium. Legacies received in each of the last two years amounted £68,000. The total receipts of the King's Fund for 1929 were £535,435.

Reports of Subcommittees.

The principal event recorded in an interim report presented by the Right Hon. J. H. Whitley, chairman of the Voluntary Hospitals (Parliamentary) Committee, was the establishment of the representative committee of the voluntary hospitals, appointed for the purposes of the Local Government Act. The report also referred to the claim of hospitals to payment for road accident cases. In this connexion the Fund is working with the British Hospitals Association.

The Earl of Donoughmore, chairman of the Management Committee, presented a report on a pay-bed insurance scheme for the professional and middle classes. The Fund is not responsible for this scheme, but the Management Committee, on behalf of the Fund, has conveyed to its sponsor, Sir Alan Anderson, an expression of sympathy and of hope for its success. The Pay Beds Committee reported that in twelve months the number of pay beds had increased from 1,005 at eighty hospitals to 1,154 at eighty-eight, and further hospital extensions including beds of this kind had since been completed and opened. A section of this report dealt with insurance schemes to enable members of the professional and middle classes to provide beforehand for the cost of maintenance and treatment in a pay bed in the event of severe illness or operations. A satisfactory report was submitted of the work of the Propaganda Committee, which is arranging exhibitions, in aid of the King's Fund and hospitals, of photographs taken by members of the Royal Family.

The Fund and Voluntary Hospitals.

The report again draws attention to the need of subscriptions and donations, legacies being unreliable sources of income. It points out that the more the King's Fund receives the more it can distribute, and the greater will be its influence in maintaining the financial stability of the hospitals in London.

BIRTHDAY HONOURS.

THE Honours List, issued on June 3rd, on the occasion of His Majesty's birthday, includes the names of the following members of the medical profession.

K.C.B. (Military).

Surgeon Vice-Admiral ARTHUR GASKELL, C.B., O.B.E., F.R.C.S., D.P.H., K.H.S.

Air Vice-Marshal DAVID MUNRO, C.B., C.I.E., M.B., Ch.B., F.R.C.S.Ed., Royal Air Force (ret.).

K.C.B. (Civil).

Colonel WILLIAM COATES, C.B., C.B.E., F.R.C.S., V.D., T.D., D.L., Territorial Army (ret.).

Knights Bachelors.

NORMAN GODFREY BENNETT, M.A., M.B., B.Ch., M.R.C.S., L.D.S., President of the British Dental Association.

HAROLD DELF GILLIES, C.B.E., F.R.C.S., Major R.A.M.C.(ret.), Chief Plastic Surgeon to the Ministry of Pensions. For valuable services in the treatment of facial disfigurement.

Professor LEONARD ERSKINE HILL, M.B., F.R.S., Hon. A.R.I.B.A., Director, Department of Applied Physiology, National Institute of Medical Research.

THOMAS EUSTACE HILL, O.B.E., M.A., M.B., C.M., D.Hy., B.Sc., lately Medical Officer of Health for the County of Durham.

Khan Bahadur BEHRAMJI HORMASJI NANAVATI, C.I.E., F.R.C.S.Ed., Bombay.

JOHN RANDALL PHILLIPS, O.B.E., M.B., President of the Legislative Council, Barbados.

C.M.G.

Major GERALD JOSEPH KEANE, D.S.O., M.D., Director of Medical and Sanitary Services, Uganda Protectorate.

HERBERT CHAVASSE SQUIRES, M.D., Director, Khartum Civil Hospital.

C.I.E.

Major-General GODFREY TATE, I.M.S., Surgeon General to the Government of Bengal.

Lieut.-Colonel WILLIAM JACKSON POWELL, I.M.S., Inspector-General of Prisons, Central Provinces.

Lieut.-Colonel HUGH REGINALD DUTTON, I.M.S., lately Principal, Prince of Wales's Medical College, Patna, and Superintendent of the Patna Medical College Hospital, Bihar and Orissa.

C.B.E. (Military).

Wing Commander HAROLD EDWARD WHITTINGHAM, M.B., Ch.B., F.R.F.P.S., M.R.C.P.Ed., D.P.H., D.T.M. and H., Royal Air Force.

M.V.O. (Fourth Class).

CLIFFORD VINEY BRAIMBRIDGE, F.R.C.S.Ed., Medical Officer, East African Medical Service.

O.B.E. (Military).

Major JOHN HARE, M.D., F.R.F.P.S., R.A.M.C.

O.B.E. (Civil).

JOHN RHODES DICKSON, M.B., Deputy Surgeon General and Medical Inspector of Health, Colony of Trinidad and Tobago.

Miss ALEXANDRINA MATILDA MACPHAIL, L.R.C.P. and S.Ed., L.R.F.P.S., Superintendent, Rainy Hospital, Madras.

Major and Brevet Lieut.-Colonel WILLIAM CLAYTON SMALES, D.S.O., R.A.M.C., lately Medical Officer of Health, Gibraltar.

Hon. O.B.E. (Civil).

ABDUL AL, Medical Officer, Hebron. For services during the disturbances in Palestine in August, 1929.

SULEIMAN SALEEM, Medical Officer, Jerusalem District. For services during the disturbances in Palestine in August, 1929.

Kaisar-i-Hind Medal (First Class).

Miss ELEANOR ISABEL DODSON, M.D., L.S.A., in charge of the Church Missionary Society Zenana Hospital, Multan, Punjab.

Miss ALICE LUCRETIA ERNST, M.D.Philadelphia, U.S.A., in charge of the Ackerman Hoyt Memorial Hospital at Jhansi, United Provinces.

JOHN EDWARD SANDILANDS, *M.C.*, M.D., D.P.H., late Health Officer, Bombay Municipality, Bombay.

HASSAN SUHRAWARDY, O.B.E., M.D., F.R.C.S., D.P.H., Chief Medical Officer, Eastern Bengal Railway, Bengal.

British Medical Journal.

SATURDAY, JUNE 7TH, 1930.

THE WORK OF THE ASSOCIATION.

In the introductory paragraphs of the Proposals for a General Medical Service,[1] which are the outstanding feature of the Annual Report of Council now before the Divisions and Branches of the British Medical Association, it is stated that "the Association is a body representing the great majority of doctors in this country and in the British Empire," and again, that the scheme itself is "in accordance with the beliefs and traditions of the medical profession, and would have its whole-hearted support." This is no modest claim, but as it is implicit in all the medico-political and ethical work of the Association members may properly inquire from time to time to what extent and in what manner it is justified. In doing so they must remember that the Association is not responsible for the creation of the problems for which it seeks to offer a practicable solution. The form of these is determined at the moment by the recent increase in the pressure of public demands upon the resources of the medical profession and the radical change in the structure and outlook of the profession as a whole. Social development rather than professional bias must determine the environment of medical practice, and specialization and sectionalization, conducive to efficiency only so long as the results of research are pooled and the several sections are prepared to accept the immediate sacrifice involved in pursuit of a common policy, not only increase the importance of securing an effective agreement upon every disputed issue but render it incalculably more difficult to do so. The production of an acceptable policy involves far more than a mere counting of heads and nice gauging of the preponderance of opinion on any point at any given moment. It is in the light of these general considerations that the work of the British Medical Association should be judged, and the current report published in the *Supplement* on April 19th and 26th provides material on which a judgement may be founded.

A very large part of the report is devoted to two comprehensive statements of policy: the Proposals for a General Medical Service, and the revised Hospital Policy. Each of these statements is the outcome of many years of work; each embodies proposals affecting at some point the conditions of practice of every section of the profession; and each is a reply to definite demands already made by the community, which in accepting the Local Government Act has placed itself in a position to make its demands increasingly effective. The Hospital Policy is the result of over ten years' unremitting effort to secure the agreement of those most closely concerned, first on the principles to be applied to the solution of hospital problems, and later about the manner of their application in circumstances continually modified by successive changes of public policy in connexion with institutional services. Throughout this period no attempt has been made to take advantage of majority decisions on any disputed point. The only object has been to attain agreement first among the hospital staffs as a whole, irrespective of their membership of the British Medical Association, and later throughout the profession. The verdict of the Representative Body of the Association in July will show whether it can be claimed that the year which has inaugurated a new era in hospital service by the transfer of the Poor Law institutions will also be distinguished by the effective organization of the profession to meet the needs of the new position. The evolution of the Proposals for a General Medical Service is of no less interest. Two years ago the demand of the Representative Body for an investigation of encroachments into private practice was the expression of a desire to protect the interests of one section of the profession. The resulting survey demonstrated the growing pressure of public calls on every branch of the profession and the impossibility of adequately meeting those calls without general agreement of the whole body as to the part to be played by each section, and without agreement by each section to accept full responsibility in the sphere of practice thus allotted to it. The report on encroachments, primarily therefore a matter of domestic politics, both showed the need and cleared the way for the constructive proposals now put forward. Here again there is no new principle at issue, though new expedients have been found for giving effect to settled policy. The central idea of the extension of medical benefit to the dependants of insured persons was accepted by insurance practitioners in 1925, and in the same year their decision was endorsed by the Representative Body. The other items of the programme have also been separately agreed from time to time as occasion has arisen. What is new is the confident assurance to the public that the profession as a whole is prepared to accept responsibility for a comprehensive service to which each section will contribute according to an ordered plan. Such an assertion may not be justified, but it is difficult to believe that professional self-determination can be achieved except on this basis.

Two more sections of the report are addressed primarily to the public. The statement on the use of anaesthetics in midwifery, being the Association's response to a public demand for an authoritative statement of professional opinion on a point on which the public conscience is troubled at the moment, illustrates another aspect of the Association's obligations. The report on tests for motor drivers is an attempt to discharge a responsibility expressly accepted by the Representative Body last year by defining the practicable limits of professional assistance in determining standards of fitness for driving motor vehicles. The manner of its production shows that the Association can at short notice concentrate on such a problem expert opinion from every branch of the profession qualified to contribute to its solution. The successful intervention in connexion with the draft Poor Law Order shows the utility of the Association's machinery for ensuring that the position of the profession is not prejudiced by departmental oversights. The progress of the Mental Treatment Bill marks a victory of organized professional opinion in obtaining an improvement, considered impracticable by the Royal Commission, in the facilities for the treatment of mental disease, and at the same time securing a substantial increase in the protection afforded to the individual practitioner carrying out his duties under the Lunacy Act. The report on collective investigation shows a successful application of the Association's machinery to the provision of means of pooling the results of individual and sectional experience for the advancement of science. Two other items deserve special notice. The failure of the negotiations for the new salaries scale for public health officers is a temporary setback, attributable indeed to a failure of representative machinery,

[1] *Supplement, British Medical Journal*, April 26th, 1930, pp. 165–182.

but not on the part of the Association. The appeal to strength as opposed to reason comes from the dissenting authorities, and the decision to ignore their defection is significant of the Council's confidence in the new scale as a reasonable settlement, generally acceptable to the profession, of points on which divided opinions have prevailed too long. The memorandum on patent law illustrates the need for securing ample time for discussion by anticipation of the difficulties requiring settlement. The urgent demand for a new formulation of professional policy on this matter comes from the section of the community most hampered by the defects of the existing law, and it seems clear that the generally accepted medical tradition is calculated to embarrass their efforts to adapt the system to modern conditions. It is noteworthy that the main difficulty in deciding upon an adequate modification of the traditional opinion lies in reconciling opinions within the medical group most directly concerned. Unfortunately, the Association was called upon to give its evidence to the Committee on Patent Law before these differences had finally been composed, and the resulting situation shows how hard it is to secure effective agreement at short notice.

These examples of the scope and method of the Association's work require far more detailed consideration than is possible within the compass of a short review, but the points touched on are in themselves sufficient to suggest the nature of the Association's claim upon the profession. For better or for worse it is at present the one recognized means for making professional opinion effective in national life. Through it the medical profession can consciously order and direct, not indeed the main stream of social development, but its own contribution to that development, adjusting itself with the minimum of waste and friction to the changed conditions of modern life. Rationalization of this quality is to be feared only by those who think to escape facts by ignoring them, and it is such rationalization that the British Medical Association puts within the reach of the profession.

THE OCCIPITO-POSTERIOR CASE.

EVERY department of medical practice has its skeleton in the cupboard—that is to say, a type of case whose unwelcome features are apt to intrude themselves at unpropitious moments and with obstinate frequency. To most young practitioners of midwifery the occipito-posterior case, discussed in our columns this week by Dr. Douglas Miller, displays most of the characteristics of the family skeleton. It even worried the great clinical master of midwifery Smellie, and he describes how the discovery of a new method of dealing with it "gave him great joy" and "opened his eyes to a new field of improvement." This new discovery (1749) was the method of instrumental rotation by forceps applied to the head in the pelvic cavity. Dr. Miller is wrong in saying that Smellie practised manual rotation; Smellie describes rotation as being done with forceps; they were short forceps, because the first cases in which he used the method occurred before the date at which the pelvic curve was added to the instrument.

The aim of midwifery to-day is to prevent difficulties, if that be possible, and if not, to foresee and prepare to meet them. The unpardonable fault is to be taken unawares by an obstetric difficulty which might have been anticipated. The careful descriptions of the methods of diagnosis in Dr. Miller's article are therefore very welcome, but it cannot be gainsaid that the diagnosis of an occipito-posterior case before labour calls for a high degree of skill and experience, only to be attained by constant practice in methods of abdominal examination. In all probability a considerable proportion will continue to escape recognition before labour, but no opportunity should be lost of trying out the useful method of rectification before labour introduced by Buist.

For the practitioner of midwifery, patience stands easily first of the cardinal virtues; and never is it more needed than in dealing with the occipito-posterior case. Careful, unhurried attention must be freely given; and, undisturbed by the slipping away of the hours, attention must be concentrated, not upon the clock, but upon the patient's progress and her general condition. Waiting may be long, but it must not be too long; and here enters that quality of clinical judgement which no teacher can impart to his pupils. Smellie, who possessed this quality in high degree, was accustomed to wait long hours, when "pains were still weak, and the gossips uneasy," giving his patient "caudle, bread, and broth." To the modern equivalents of these invalid delicacies we now add scopolamine and morphine, or maybe some other narcotic of which Smellie knew nothing. Fortunately patience and watchfulness will be rewarded by spontaneous rotation in a large majority of cases.

In a series of 750 cases taken from the Edinburgh Maternity Hospital Dr. Miller[1] found that spontaneous rotation occurred in 63 per cent. of them; most writers on the subject have put the proportion much higher than this. After forward rotation had occurred, Dr. Miller found that 90 per cent. delivered themselves, the remainder requiring only a low forceps operation. Forward rotation is accompanied by descent of the head, which can be followed by easily observed and well-known signs. An occipito-posterior case may accordingly be carried through without a single internal examination having been made, if forward rotation occurs. It appears that little can be done to assist spontaneous forward rotation, and Dr. Miller's suggestion with regard to posture in the second stage is unconvincing; effective uterine action is probably the most important factor in bringing it about. When forward rotation does not occur spontaneously the aspect of the case is profoundly changed. In the series of 750 cases already referred to, those in which spontaneous rotation did not occur were attended by a maternal mortality of 2.0 per cent. and a foetal mortality of 27.3 per cent.; those, on the other hand, which did rotate spontaneously showed no maternal mortality at all, and a foetal mortality of only 2.7 per cent. Even when by backward rotation into the sacral hollow an occipito-posterior has become a "face to pubes" case, spontaneous delivery is not uncommon in a multipara with a strongly acting uterus and plenty of pelvic space. In all other circumstances "face to pubes" cases are marked out for operative delivery.

The unrotated cases—that is, those in which the head remains in the oblique diameter—call for the exercise of a close discriminative judgement in the choice of the right moment to intervene. As long as the head continues to descend, however slowly, forward rotation may be hopefully awaited. Even when progress has become definitely arrested, an hour or two's sleep, induced by morphine, may be followed by a complete change in the character of the uterine action, which will lead to rapid progress and a normal termination. When the "gossips are uneasy" it is often difficult for the practitioner to convince them that patience, and still more patience, will give the best results; and unless he is sure of himself, and of the wisdom of his advice, he will often be driven into a

[1] *Transactions* of the Edinburgh Obstetrical Society, vol. 47, p. 77.

course of action from which his own better judgement recoils. Although the practice of midwifery calls for a high standard of technical knowledge and manipulative dexterity, it calls even more for calm judgement and for that blend of prudence with audacity which marks out the man of character. A series of occipito-posterior cases in private practice furnishes a salutary exercise in the development of character, which, painful as it may be at the moment, will never be forgotten.

With the exception of the method of manual rectification, which Smellie was not acquainted with, we have now no method of delivery in occipito-posterior cases which he did not practise. Some he treated by version, others he rotated with his short forceps, others he delivered face to pubes; in some of the latter he pulled out the forehead and face first by traction in a backward direction, delivering the head eventually as an anterior chin. The modern method of episiotomy he did not practise, but he was careful to dilate the ostium vaginae (he called it the os externum) digitally before attempting to rotate with his forceps. Probably many an episiotomy might be avoided nowadays if a little time were devoted to this simple manœuvre. Potter, who has done so much to popularize the method of delivery by version in the United States, owed a great deal of his success to careful preparatory dilatation of the vaginal canal; in a picturesque American phrase he called it " ironing out " the vagina. It is after all but an extension of a method commonly employed by Smellie.

The modern obstetric forceps is an unsuitable instrument for rotating an occipito-posterior head, and attention is now rightly concentrated upon the manual method of which Dr. Miller gives a clear description. It is a procedure which the vast majority of medical students have only seen performed upon the obstetric " dummy." As in the case of all surgical operations, the first step in learning it is to attempt to perform it; yet a very young practitioner may be called upon to perform it at any moment in the early days of entering upon practice, and his imperfect acquaintance with the method may result in loss of valuable life. The occipito-posterior case is only one instance among many in which inadequate training in midwifery may lead to serious disaster. The provision of greatly increased clinical facilities for training students is still the most urgent obstetric problem of the moment. Our national schemes for a maternity service will inevitably break down if founded upon the insecure base of deficient practical training.

THE BIRTHDAY HONOURS.

THE list of honours conferred by the King on the occasion of His Majesty's sixty-fifth birthday includes the names of a number of medical men whose valuable work in varied capacities is well known to the profession. Surgeon Vice-Admiral Arthur Gaskell, Medical Director-General, R.N., Air Vice-Marshal David Munro, until lately Director of Medical Services, R.A.F., and Mr. William Coates of Manchester, who has identified himself with the Territorial Medical Service, are deservedly promoted K.C.B. The honour of knighthood to be conferred on Professor Leonard Hill, Dr. Eustace Hill, Mr. Harold Gillies, and Mr. Norman Bennett, recognizes distinguished work in pure and applied physiology, in hygiene and public health administration, in plastic surgery during the war and after, and in the science and practice of dental surgery. Dr. John R. Phillips, president of the Barbados Legislative Council, and Dr. B. H. Nanavati, formerly honorary surgeon to the Viceroy of India, receive the same honour. Professor J. Arthur Thomson of Aberdeen, though not a member of the medical profession, has long been concerned in medical education, and his knighthood, like the C.H. conferred on Miss Margaret McMillan for her pioneer work in founding school clinics and nursery schools, will be welcomed by our readers. The full list of medical Birthday Honours will be found at page 1058, and to all the recipients we offer congratulations.

THE BRITISH DENTAL ASSOCIATION'S JUBILEE.

THE fiftieth annual meeting of the British Dental Association took place last week in London under the presidency of Mr. Norman Bennett. The meetings were highly successful (save for the fact that a motor-car accident prevented the Minister of Health from delivering the inaugural address), and there was a good attendance of members and well-sustained discussion. A fund aiming at £20,000 was launched during the meeting with the object of obtaining larger headquarters than the premises in Russell Square, which the association during the ten years of its occupancy has quite outgrown. The membership is now just over 4,000, having doubled itself within eighteen years. Many Dominion and Colonial representatives attended the meeting, and opportunity was taken for conference on the promotion of closer union between the dental associations of the Empire. One of the most instructive of the discussions related to dental education, in which British and American methods were compared. It was opened by Mr. M. H. Garvin of Winnipeg, president of the Canadian Dental Association, who described the conditions of dental education in Canada. Mr. Lewin Payne, who has recently visited Canada and the United States to investigate dental education in those countries, gave some interesting impressions. Medicine and dentistry on the other side of the Atlantic are looked upon as two distinct professions, and the Canadian dental schools do not regard dentistry as a definite branch of medicine. The courses of study in Canadian schools Mr. Payne found to be much more closely allied to those in the United States than to the British curriculum. The preliminary science examinations are not the same in America for medical and for dental students, with the result that it is difficult for the dental student afterwards to take a medical degree; indeed, Mr. Payne was told that it might involve a period of not less than nine years for a dental student in America to become medically qualified. Professor W. H. Gilmour, who has also lately visited Canada, pointed out that in America a diploma or degree conferred by a university gave no right to practise in a particular Province or State; that right was granted by the Provincial or State examining board. Academically Professor Gilmour thought that dental education was on sounder lines in Great Britain than in America, by reason of the closer association with medicine and surgery; but technically he found the teaching in America very far superior, although perhaps it was a little over-organized and the students were liable to be " spoon-fed." Colonel T. A. Hunter of New Zealand said that he had always held that the standard for the Dominions should be one fixed by the General Medical Council in this country. For some time that state of affairs did obtain in New Zealand, but later, in addition to the university degree recognized by the General Medical Council, New Zealand had set up another and lower qualification, entitling its holder to practise in that country, but not elsewhere. He thought that that step was now generally regretted. Speakers from New Zealand and other Dominions deplored the lack of post-graduate facilities in Great Britain, with the virtual compulsion upon them to go to the United States. The principal clinical discussion in the meeting took place on a paper by Mr. F. W. Broderick on the differentiation of simple marginal gingivitis for commencing pyorrhoea. Mr. Broderick suggested that early pyorrhoea was really antagonistic to caries, the causative factors of each being opposite. This view was contested by

Mr. F. St. J. Steadman, who said that he could show Mr. Broderick many cases of active caries and active pyorrhoea existing at the same time, and the etiological factors involved were the same—namely, the lodgement of sticky carbohydrate food. The general opinion in the discussion, however, was in favour of Mr. Broderick's contentions. On the social side the meeting was equally a success. The jubilee dinner brought together a large gathering of members and guests at the Hotel Great Central. Among the speakers were Sir Arthur Robinson, Secretary to the Ministry of Health, who mentioned that every year a sum of £3,000,000 of public money was spent on dentistry, the arrangements covering one-third of the population of Great Britain; and Sir Francis Dyke Acland, chairman of the Dental Board, who commented upon the remarkable advance in honour and repute which the profession of dentistry had made of recent years. Finally, mention must be made of the *Jubilee Book*,[1] which has been prepared by the association as a souvenir of the occasion. It contains an illustrated synopsis of the association's history set out in the briefest chronological form. It is possible thereby to trace the beginning and development of many things which are the commonplaces of modern dental experience, such as the growth of the public dental service, the tightening up of legislation, and the raising of the ethical standard. The address of the first president, Sir John Tomes, is reproduced in full. It was delivered at the Dental Hospital, Leicester Square, in 1880, and ended with the words: "We are travellers on a road which leads to professional learning. The Dentists Act [of 1878] is our permanent way, the Medical Council and the medical authorities our locomotion, the dental practitioners must provide stokers and fuel, and our young men will be the passengers."

AN EXHIBITION OF ANATOMICAL ILLUSTRATIONS.

AN extremely interesting and carefully arranged exhibition has been prepared in the Anatomical Department of McGill University, Montreal, on the history of anatomical illustration. The university is fortunate not only in possessing a good medical library of its own, but also in having the Osler Library in the same building. The two together provide a great store of material for exhibitions, of which the present display is an example. A very full catalogue of the exhibits has been printed,[2] with an introductory historical sketch of the subject, in which it is pointed out how the older illustrations of anatomical works, while lacking our modern precision and clarity, were often superior in artistic taste, and, at their best, were hardly inferior in accuracy. The point is well supported by reference to such masterpieces of anatomical drawings as those of Leonardo da Vinci, Dürer (in his *Menschliche Proportion*), the woodcuts in Vesalius (not by Titian, but by one of his pupils, Stephen of Calcar), and the very fine engravings in William Cheselden's *Osteographia*. In the case of Leonardo's work, of course, facsimiles only were available for this exhibition, but the Dürer shown is a first Latin edition (1532). The first and second editions of Vesalius, *De Humani Corporis Fabrica*, are both displayed; between the two libraries there are two copies of each of these, and the Cheselden is the the very sumptuous 1733 edition. Eustachius, Fabricius, Descartes (his *De Homine*, published sixteen years after his death, and containing a "dissected" plate), are amongst those whose works are represented by first editions. An unusually rare and interesting volume displayed is Gautier d'Agoty's *Essai d'anatomie* (1745), bound up with his *Myologie complette* (1745), and *Anatomie de la tête* (1748)—a series of elaborately coloured, but not particularly accurate, anatomical plates. It represents one of the earliest uses of coloured mezzotinting in anatomical illustrations. The method was invented by Le Blon, who taught it to Gautier. The exhibition will be kept open until after the Annual Meeting of the British Medical Association in Winnipeg from August 26th to 29th. It is hoped that those who pass through Montreal on this occasion will find time to visit the Medical Building of McGill University, in which these libraries are housed and this exhibition is on view.

THE EXPLOSION HAZARD IN ANAESTHESIA.

A REPORT has lately been issued by a committee of the Council on Physical Therapy of the American Medical Association[1] dealing with the risks of explosion arising in the use of anaesthetics. The danger of fire and explosion associated with ether vapour has long been recognized, but many gaseous mixtures now used—for example, nitrous oxide with ether, or ethylene with oxygen—are still more highly explosive. A case is recorded of a fatal explosion of an ethylene mixture in the air passages of a patient, caused by the use of a cautery, although the apparatus for administering the anaesthetic had actually been taken out of the room. It is stated that such explosions can be caused by the electrical charges produced by friction of rubber apparatus, blankets, etc., and that such electrification can be produced even by dust particles carried in a current of air. The suggestion is made that by maintaining a high relative humidity—about 60 per cent.—in the air of the operating theatre there will be sufficient condensation of moisture on the apparatus to prevent any dangerous electrical charges from accumulating in this way; an additional advantage of a moist atmosphere is that there is less drying and cooling of viscera exposed in the course of the operation. It is, however, an expensive matter to install machinery for keeping the air of the theatre constant as regards temperature and humidity. The committee recommends that rubber should be eliminated as far as possible from the construction of apparatus designed for use with explosive anaesthetic mixtures, flexible metal tubing of specially light pattern being used, and arrangements being made for "earthing" not only the apparatus but even the persons who are liable to come into contact with it. Ether or ethylene should not be used in any operation involving the use of a cautery or diathermy. The fact that explosions are extremely rare in connexion with the administration of anaesthetics is not, it is submitted, due altogether to any conscious efforts made to provide against this risk, but rather to the fortunate circumstance that the conditions under which anaesthetic mixtures will explode are seldom approached in the actual use of these substances: the figures derived from tables of flash-points, etc., are obtained under conditions quite unlike those of the average theatre. Professor Yandell Henderson, reporting on behalf of the committee on anaesthesia accidents of the American Medical Association,[2] makes a series of recommendations which in general correspond with those put forward by the Council on Physical Therapy. As might be expected, he definitely favours the use of modern anaesthetic apparatus, even with ethylene as the anaesthetic, summarizing his view in the statement that an anaesthetic or an apparatus that is liable to occasional explosion, inducing perhaps one death in a hundred thousand or more anaesthesias, is preferable to modes of anaesthesia free from the hazard of explosion but involving a far greater hazard of post-anaesthetic deaths. Modern anaesthetic apparatus, he argues, is the most effective means yet devised for counteracting pulmonary complications, which are the principal causes of post-anaesthetic fatalities; it permits accurate control of the administration of volatile and gaseous anaesthetics, prevention of cyanosis by means of oxygen, prevention of acapnia by rebreathing, rapid induction of anaesthesia with nitrous oxide, rapid termination of anaesthesia, and

[1] *Journ. Amer. Med. Assoc.*, March 29th, 1930, p. 918.
[2] *Ibid.*, May 10th, 1930, p. 1491.

especially hyperventilation and full expansions of the lungs with carbon dioxide. But even if it is true that explosion is statistically the rarest accident of anaesthesia, those who have the responsible task of giving anaesthetics, especially with the more modern and elaborate apparatus, are still faced with the duty of protecting patients against this hazard as they are against the commoner risks of anaesthesia.

"CONTACT" EXAMINATION OF CHILDREN.

THE essay entitled "Tuberculosis in public school children," which has been reprinted from last October's number of the *American Review of Tuberculosis*,[1] marks a distinct advance in the method of "contact" examination of children. The conclusion that the authors draw from their experience is this. No reliance may be placed on the absence of physical signs, and good apparent general health in the child, not even on steady increase in body weight. Definite grades of the disease in its preventable stage can be detected much earlier than was suspected by the use of the tuberculin reaction and the *x* ray. There is no doubt that the incidence of infection and clinical disease differs in different communities and in different countries: in this experience it is to be noted that the schools contained many coloured children, who are more susceptible than the white, and in whom a different type of lesion is found. The numbers, therefore, are probably not the same that would emerge from a similar investigation in other countries. The authors have produced a valuable piece of work by suggesting a routine method for thorough "contact" examination. The intracutaneous tuberculin test is used, which they consider far more sensitive than the Pirquet test, but they do not mention its practical difficulties, such as the need for repetition, and the possible production of severe reactions. Undoubtedly the most interesting and important part of the book is the *x*-ray work. X-ray examination was made of all tuberculin reactors. The improvement in technique of interpretation and of accurate localization of lesions makes stimulating reading. The routine examination suggested is very laborious and very expensive, but it would appear that if "contact" examination and preventive treatment is to be done at all some such system must be adopted, and adopted as a standard. Anything less searching is only a waste of time and money. The schematic classification of pulmonary tuberculosis in childhood and adolescence by Dr. McPhedran with which the essay ends is excellent and will probably appear in all future textbooks on the subject.

THE GORDON MEMORIAL COLLEGE.

IN the deluge of deadly dull reports poured forth throughout the year by countless bodies and institutions, Governmental and otherwise, there occurs from time to time a record of a body whose work thrills by its inspiration. Such is the Gordon Memorial College at Khartum, of which the report for 1928 by the executive committee and trustees, presented at a meeting in London last July, has now been published. Initiated by the late Lord Kitchener thirty years ago as an institution for the education of the youth of the Sudan in a manner suitable to their environment and capacity, the college now has accommodation for between 500 and 600 boys, most of whom are boarders. It is hoped that by the end of the present year the output of boys who have completed the full secondary course will be 120 annually, so that the recent situation, when only 62 boys were available to fill 145 vacancies in Government employment, will not recur. The number of tutors, at present apparently fourteen, is to be increased, and in future all tutors will undergo a year's course of training at the London Day Training College before going out to Khartum. Natives of the Sudan are being employed on the teaching staff, some of them having taken a course of studies at the American University at Beirut. The report describes the progress of the boys in sections for engineering, science, accountancy, clerical work, teaching, and in a kadi's section. In the boarding houses discipline has been maintained efficiently under the prefectorial system. Football, rounders, gymnastics, and scouting are indulged in by the boys, who come of Arab, Sudanese, Muwalad, Berberine, and Abyssinian stock. Instructional workshops are run in connexion with the college; and a large amount of research work is done in sections for bacteriology, tropical diseases, chemistry, entomology, geology, and antiquities. In addition to the activities of the college, progress in education in the Sudan is shown by the rapid growth in number and popularity of the subsidized khalwas or village schools; and there is an increasing demand for elementary vernacular education for girls. The now educated Sudanese demand wives "who can give them the order and cleanliness in their homes which they have been taught to appreciate."

CONGRESS FOR SEX RESEARCH.

A PRELIMINARY programme has now been issued of the second International Congress for Sex Research, to be held in the House of the British Medical Association, Tavistock Square, London, from August 3rd to 8th. The provisional arrangements include an informal reception on the evening of Sunday, August 3rd; a presidential address by Professor F. A. E. Crew on puberty and maturity, on the morning of August 4th; and papers relating to puberty and maturity, the biology of testicular and ovarian function, hormone therapy, sexual psychology and biology, and the biological and therapeutical aspects of the control of human fertility, during the succeeding sessions of the congress. Social functions will include a motor excursion to Down House, a visit to Cambridge, various sight-seeing tours, and receptions and concerts. Members of the congress who wish to present a paper are asked to send a copy of it, together with an abstract, to the Congress Secretary, Department of Animal Genetics, the University, Edinburgh, not later than June 15th; those who have already offered a paper are asked to submit the title to the secretary at once. The maximum length of each paper to be published in the *Proceedings* is 3,000 words. Some account of the arrangements for the congress appeared in the *Journal* of May 10th (p. 874); further arrangements now completed include plans for accommodating members in university hostels and hotels, banking facilities with the branch of the Westminster Bank Ltd. situated in the House of the British Medical Association, and provision through Thomas Cook and Son, Ltd., who have been appointed travelling agents to the congress, for conveying members to their quarters on arrival in London. Particulars of these and other preparations for the congress may be obtained on application to the Congress Secretary.

WE regret to announce the death, on June 1st, of Dr. Robert McKenzie Johnston, consulting surgeon to the ear and throat department of the Royal Infirmary, Edinburgh, and a Past President of the Royal College of Surgeons of Edinburgh. An obituary notice will appear in our next issue.

WE regret to announce the death at Torquay of Dr. H. Cooper Pattin, for many years medical officer of health for the city of Norwich.

A COURSE of instruction in the technique of tissue culture will be given at the Strangeways Research Laboratory from July 1st to 29th. Only a limited number of applicants can be received. Notification from those wishing to take the course should be sent to Dr. H. B. Fell, Strangeways Research Laboratory, Cambridge.

NINETY-EIGHTH ANNUAL MEETING

of the

British Medical Association,

WINNIPEG, 1930.

THE CENOTAPH, WINNIPEG.

AT the invitation of the Canadian Medical Association the ninety-eighth Annual Meeting of the British Medical Association will be held at Winnipeg this summer, under the presidency of Professor W. Harvey Smith, who will deliver his inaugural address on Tuesday, August 26th. The scientific and clinical business of the meeting is being organized in fourteen Sections, which will hold their sessions on Wednesday, Thursday, and Friday, August 27th, 28th, and 29th, the mornings being given up to discussions and the reading of papers, and the afternoons to demonstrations and special addresses. The names of the Officers of Sections, with provisional programmes of work and other preliminary notes, were published in the *Supplement* of May 10th, and further details of the arrangements will appear in later issues. Members who propose to take part in the meeting should write at once for particulars about the journey to the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, London, W.C.1.

We publish below the fifth of a series of descriptive and historical notes, written for the occasion.* In this article Dr. D. A. Stewart, superintendent of the Manitoba Sanatorium at Ninette, and president of the Manitoba Historical Society, introduces British visitors to the historic background of the places they will see. Those visiting Canada for the first time, and especially those who make the trip from coast to coast, are apt to be overwhelmed by the immensity of the country; Dr. Stewart's vivid sketch should enable them to form an idea of the way in which the country was settled, and thus add much to their enjoyment of the tour.

AN ADVENTURE ACROSS CANADA IN 1930.

WITH NOTES ON EARLIER ADVENTURES AND ADVENTURERS.

IN the middle of August, 1930, two parties of physicians and surgeons of Great Britain will set out towards Canada upon a voyage of discovery, exploration, and adventure. To all who sail in the *Duchess of Bedford* and the *Duchess of York* are granted herein and hereby in full the rights and privileges King Henry VII bestowed upon John Cabot and his sons in 1497: "Full and free authority, leave and power to sail to all ports, countries, and seas . . . to seek out and discover whatever isles, countries, regions or provinces . . . which before this time hath been unknowen."

As you scan the westward horizon for the hazy blur of landfall—if you can only adjust your glasses to look back 930 years, to a time when England was still Saxon—you may see an open Viking boat, with Leif, son of Eric the Red, nosing in at Labrador and calling it Helluland, the land of flat stones, or at Newfoundland, calling it Markland, the land of trees, or sailing away to Nova Scotia, or still southward to find Vinland, the land of vines and grapes. Or, if you can focus at 433 years ago, you may have a glimpse of bunty little turreted vessels with John Cabot and company touching at the New-found-land which he reported as "Seven hundred leagues west of Ireland" and "the country of the Grand Khan." So the grudging purse of Henry bestowed "Item, to him that found the new isle, ten pounds."

Follow Jacques Cartier.

All the way up the St. Lawrence you will follow in the very wake of the real discoverer of Canada, Jacques Cartier of St. Malo. In 1534 he entered and named Belle Isle Strait, thought (as you probably will also) that the north coast of the gulf was "the land God gave to Cain," discovered the island which became Canada's smallest province, and sailed on a hot day into a bay he called Chaleurs. Next year he adventured on, as you will, up to Quebec and even to Montreal.

Anchored at the mouth of the St. Charles, beside the Indian Stadacona, which became the French Quebec, in the winter of 1535–36, the bold captain, turned perforce to our craft, entered in his log a very vivid description of scurvy, and an account of the first white man's autopsy made in Canada.

"Some lost all strength . . . legs swollen and inflamed, sinews contracted and turned as black as coal . . . legs blotched with purple-coloured blood . . . mouths so tainted that the gums rotted away down to the roots of the teeth, which nearly all fell out. . . . And because the disease was a strange one the Captain had one body opened. . . . And it was discovered that his heart was completely white and shrivelled up . . . his liver was in good condition but his lungs were very black and gangrened . . . his spleen for some two fingerbreadths near the backbone was also slightly affected, as if it had been rubbed on a rough stone."

"There were not three men in good health" [when the Indians suggested hemlock tea]. "In less than eight days a whole tree . . . was used up, and produced such a result that had all the doctors of Louvain and Montpellier been there with all the drugs of Alexandria they could not have done so much in a year as did this tree in eight days. . . . They were cured of *all the diseases they had ever had . . . even the French pox.*"

Historic Quebec.

Four centuries of history—French colonial, British colonial, and Canadian—lie side by side in the city and province of Quebec as in a museum. In narrow streets

* See *British Medical Journal* January 4th, 1930 (p. 32); February 15th (p. 309); March 22nd (p. 555); May 10th (p. 875).

and break-neck lanes, in old houses and ancient customs, in obsolete citadel and city gates, in Wolfe's Cove and the Plains of Abraham, the past lives within the present.

Up the St. Lawrence, from the days of Cartier, Champlain, Frontenac, La Salle, have toiled innumerable canoes with explorers, adventurers, traders, soldiers, priests; and down the St. Lawrence many a returning voyageur, with peltries and, perchance, wounds, and tales of new lakes, rivers, and tribes, and still new lands and vistas to westward.

Almost every homestead, even of to-day, with its scant-roofed, big-chimneyed house of stone, and long wooden barn, was born in adventure. When its roofs were raised and its fields cleared the musket had to keep daily company with the axe and the ploughshare. No wonder that the homes hug the river banks like a struggling village, with narrow ribbons of farms stretching back almost as far as eye can reach. Here life goes on, even in this day of radio, almost as placidly as a century ago.

Three Rivers was an early outpost of trade and defence against Indians. It now fights in the same spirit its infant mortality and tuberculosis death rate. Here, beside huge paper mills, rafts of pulpwood—the food for the mills—float in the same waters with steamers that take the finished product anywhere in the Seven Seas.

The Romance of Montreal.

What city was ever planned and built with the romance of Montreal? What other settlement anywhere was ever founded, the hospital first, and the settlement a kind of afterthought to supply patients for the hospital? That was an age of the seeing of visions and the dreaming of dreams. One pious lady in France had a vision of a hospital in this very nook of the wilderness; another pious lady gave money, devout and chivalrous Maisoneuve lent his sword willingly to the enterprise; and, to the scandal of all practical persons and the chagrin of viceregal Quebec, the visionaries landed in May, 1642, and celebrated mass at a rustic altar festooned with flowers and lighted with fireflies for tapers.

Here stalwart settlers fought Indians and, even worse, the dominance and monopoly of official Quebec. Times have changed, and now Montreal sits at the receipt of custom.

Built on an ample island, backed by a mountain, fronted by a broad river and a fine view of distant hills, with world-famous university and hospitals, the wealthiest and most populous community in the Dominion, a seaport a thousand miles from the sea, Montreal is no mean city. It is almost two cities in one, bilingual, and a paradise for sign painters, for all signs must be painted twice.

Above Montreal, to the Great Lakes, are rapids; the first, which blocked the way to the Orient, called in grim humour, "Lachine." These rapids are canalized only for small craft, but the building of larger canals to bring ocean vessels to Lake Superior and the very heart of the continent is Canada's next big job, though Montreal has doubt about it yet.

Ottawa.

If this were not 1930, but a century earlier, we would travel westward by that wonderful craft the "six-fathom" birch bark canoe, carrying four tons of freight and a crew of ten. At the very last chapel on the edge of the wilderness a century ago, but still to be seen from train window,

> "Soon as the woods on the shore looked dim
> We'd sing at St. Anne's our parting hymn,"

and push up the turbulent Ottawa. At the Chaudière Fall, where there was a big carrying place or "portage," a hamlet of voyageurs and trappers grew up, then a straggling village of lumbermen, Bytown; then, Cinderella-like, a fairy wand touched the place, and, lo! it became Ottawa, the stately capital of Canada.

Besides Parliament Hill and many things else to see, be sure to remember the National Museum, where some fine specimens of prehistoric residents of Canada, especially of the Upper Cretaceous formation of Alberta, are to be found, among them: *Eoceratops canadensis, Styracosaurus albertensis, Brachyceratops dawsoni, Hadrosaur edmontosaurus,* the Cretaceous theropodous dinosaur, gorgosaurus, etc.

Nine Provinces, but Six Canadas.

Ottawa is in Ontario, but as near Quebec as a loop of the river will allow it to be. Before confederation and the forming of the Dominion in 1867 there were two Canadas—Lower Canada or Quebec, and Upper Canada or Ontario. Besides these there were three maritime colonies and the whole west and north, which was little better than a no-man's-land. Now there are nine provinces, and northern territories besides.

In reality there are something like six fairly distinct Canadas. First, the Eastern Maritimes: Nova Scotia, New Brunswick, and Prince Edward Island, chiefly Scotch-English, thoughtful, thorough-going people, with farming, fishing, fruit growing, lumbering, and coal mining as the chief industries—and one of the chief exports, university professors. Next comes Quebec, extending from the Atlantic along the north side of the Ottawa almost as far west as Toronto, its people very largely French, industrious, thrifty, domestic, with farming, lumbering, and paper making as chief industries. Third, Ontario, which extends from near Montreal to near Winnipeg, and from the Great Lakes to James Bay, largely English-Scotch-Irish, central, populous, and dominant among the provinces, with almost all the various industries of soil, water, and rock. Fourth, the three prairie provinces of Manitoba, Saskatchewan, and Alberta, young, optimistic, and progressive, Anglo-Saxon chiefly, but with an increasing mixture of the races of central Europe, largely wheat-growing, but more and more looking northward to resources of furs and mines. Fifth, the Pacific Coast province, British Columbia, with its sea of mountains, its mines, rivers, timber, its fair fruit-filled valleys, and seaports in touch with the Orient. Sixth, the north country from east to west, and bounded to the north by the Arctic, long sealed, but now opening to the magic keys of aeroplane and wireless.

Toronto.

A century ago the new and struggling colony of Lower Canada had many small centres; but little "Muddy York," on the shore of Lake Ontario, outstripped the others, and now, as the fair City of Toronto, dominates the great province of Ontario, the centre for legislation and the chief centre for education, finance, and commerce. With the development of extensive mines in the Ontario hinterland, Toronto has become in the past few years mineral-minded also. Above all else industrious, substantial, church-going, and very sure of herself as the quintessence of Canada—you will find Toronto a fine city of worthy citizens.

Lakes and Great Lakes.

Canada is pre-eminently the land of lakes—lakes small and large, known and unknown, unnumbered and innumerable, but tens of thousands of them, quite likely hundreds of thousands. Aeroplane maps show often hundreds where old maps have none. Not a few among them are really great lakes, but the name "Great Lakes" is always reserved for the familiar half-dozen that maps show like a cluster of fruit hanging on the stem of the St. Lawrence. They are really freshwater inland seas, shared between us and the people of the United States, that give a waterway to the very heart of the continent.

What changes these shores and channels have seen! What differing errands and what varying craft! First the frail bark canoe of silver birch slinking in the shadows of the dark lee shore, filled with eager savages, vermilion-painted, silent, at war.

Then discoverers, explorers, adventurers, priests, first of France, then of Britain also, toiling up the channels all the long June days, with bivouac and guard at night, with trinkets to trade for peltries, writing down in scant journals and Jesuit "relations," and sketching in crude charts this new world unrolling as a scroll before their advance.

Then the traders. We have seen that the canoe route from east to west avoided the lower Great Lakes—the haunts of the Iroquois, implacable enemies of the French—and reached the upper lakes by the strenuous Ottawa and other such turbulent streams. Here, even in the late seventeenth century, French trade dribbled in, and was well established in the early eighteenth. In the later

eighteenth it reached its zenith, but now no longer distinctively French. Indeed, the "North-Westers," who formed in 1783 the loose-jointed North-West Company, with eastern headquarters at Montreal and western at the head of the lakes, was largely made up of McDonalds, McGillivrays, McKenzies, McTavishes, and others of their race for whom the Highlands of Scotland were still uncomfortable since Culloden. These were the "bourgeois," "proprietors," "partners," "traders," "clerks." All the voyageurs and some of the traders were still French Canadian.

The Great Fur Parliament.

The annual meeting was first at Grand Portage, and when that was found to be American territory, after 1802, at Fort William. Here for six weeks met hundreds of men of varied types. Up from the east came the swarthy Montreal brigades, with sweating, singing crews. Their "lake" or "six-fathom" canoes were remarkable craft. Two men could carry them over a portage, yet they carried four tons of merchandise and a crew of ten or twelve. Faster travelling, lighter "express" craft, breasting waves on cape-to-cape "traverses," carried the aristocrats of the trade, the eastern partners. Down from the lonely posts of the far west, even from the Arctic Circle, came the "wintering partners" and traders. Here, in halls hung with portraits and trophies, west met with east in state, with skirl of official pipes, to tell the conditions of trade, unfold new maps, establish new posts, explore new territories, suppress new revolts, circumvent new "oppositions," and especially to challenge the "English" company of adventurers which "traded into Hudson's Bay," as this, the Canadian company, followed the Great Lakes route.

At this great fur trade rendezvous—half-way up for the trading goods, half-way down for the peltries—all was bustle. Bales of blanket cloth and duffel, packages of flintlocks and knives, kegs of gunpowder and rum, must be unloaded from the "six-fathom" "lake" canoes, allocated, retailed, distributed, made into ninety-pound packages for the "four-fathom" "northern" canoes (canots du nord). Packages of peltries from every river in the north, already six months on their way, were sorted and repacked for the returning brigades. Here for six weeks men of all ranks in the trade, "proud North-West bucks," mingled, told their tales of adventure, smoked their pipes, renewed acquaintances, drank fierce toasts with their "regales" of rum, and fought out their feuds. Then the "Northmen" or "Winterers" turned to their far posts and their dusky families, and the "pork eaters" or "comers and goers" to their eastern homes and farms and families, the lords of the trade to Montreal and their club-house on Beaver Hill.

The Romance of To-day.

The day of the birch bark trade canoe is gone, indeed it became much quieter after the rival companies amalgamated in 1821, when the much shorter route by "the Bay" was used and the heavier York boat developed. But the Great Lakes have still their distinctive life and traffic and colour. If the pulse of lake traffic be counted at some such point as the Detroit River, it will be found that the gross tonnage enables our American friends, who share it, to make the kind of superlative statement they are fond of—greater than in any other strait or channel in the world. What will it be when the St. Lawrence channel is opened for sea-going vessels and a Glasgow tramp brings cottons or tweeds or boiler grates right up to Thunder Bay, or a Liverpool freighter sloughs its barnacles while taking on a load of wheat in the Kaministiqua?

The lake traffic is largely bulk traffic, whole loads of wheat or ore, coal or pulpwood; and the predominance of such loads has developed peculiar types of carriers, found nowhere else on lake or sea. Smudges on the sky line gradually take form as low-bellied freighters, dachshunds of navigation, two boats and a half long and half a boat high; long, low-lying craft, mere lines on the water, with quarters fore and quarters aft, and half a mile of deck between, bluff-bowed, with thirty hatches or more, steady-going, deep-voiced, grunting scant greetings as they pass. A few "whalebacks" still may be seen. It is near December when the fleets roll in, ice-clad, take on a cargo of wheat, tie up, and so give storage all winter. In early spring they smash through behind the ice breaker, and a new season has begun.

From the birch canoe of the redman, the "six fathom" of the trader, the *Griffin*, the first sailing vessel of Tonty, built at Kingston and lost—literally lost—in Upper Huron, and which, like the Flying Dutchman, is said still to haunt the lakes, to the floating palaces in which many of you will embark, the whole history and traditions of the craft and sailors of the Great Lakes might take their places very creditably beside those of any of the Seven Seas.

The Middle West.

Of the six different Canadas already indicated it is the Canada of the prairies that has the high honour of being host to the British Medical Association. The adventurers of 1930 enter this region from the "Head of the Lakes," as most of the earlier explorers did, and here and there parallel, or cross, the old canoe routes. At the Lake of the Woods and Minaki you pause beside them. If this meeting of the British Medical Association had been convened either in 1832 or in 1932 you might have chosen to come in along the trails of other adventurers, by the nearer Hudson Bay route. Parts of Manitoba and Saskatchewan, strange to say, are actually nearer to Liverpool than New York is. These advantages of the narrower North Atlantic, the great bay gouging in almost to mid-continent, and the shorter canoe voyages "The Company of Gentleman Adventurers Trading into Hudson's Bay" had over the rival "North-Westers" of Montreal and Fort William.

Manitoba extended to the Hudson Bay and became a maritime province so very recently that even her own people as yet scarcely know that while Shakespeare was still an active playwright, in 1612, two years after Henry Hudson entered the great bay, Thomas Button, with a letter in his pocket from the royal James to the Emperor of Japan, first raised the flag of England on Manitoba soil. Where Manitoba's new seaport, Churchill, is now growing up, Jens Munck from Denmark lost his whole two crews but two men, from scurvy, in the winter of 1619–20, the captain and the two men curing themselves with the first grass of springtime and sailing the smaller craft home.

Prince Rupert got his charter and monopoly in 1670, but for nearly a century the French fleet kept the Company from having quiet possession. About 1739 La Verendrye began his "search for the Western Sea," by the lake route, built his principal Manitoba fort in 1738, explored north-west and south-west almost to the mountains, and opened up a trade which the French maintained until about 1760. Their successors, the Scotch-English-French "North-Westers" from Montreal, using the lake route, were for fifty years the keenest rivals of the "English" Company of the Hudson Bay. Their "opposition" kept some sort of bounds, until the Selkirk settlers, with a sheepskin title to the whole territory by virtue of ten shillings lawful money paid in London, formed a third party. With the eternal triangle, as usual, came mischief. There were laws made and laws broken, intrigue, bloodshed, litigation, and finally, in 1821, amalgamation.

When peace had been thus restored, and when their earlier difficulties had been overcome, the Red River settlers, isolated in the midst of a continent, almost as though on a coral island in mid-Pacific, developed a unique and, in many ways, idyllic life, which the "old timers" who had survived the coming of railways and settlers, immigrants, and "civilization," look back upon with some regrets. In the convention city will be found still some links with the past, among them the gateway of Fort Garry, in which as a youth R. M. Ballantyne pushed a reluctant quill over ledger pages and dreamed romances. At that time two community buffalo hunts each year yielded two harvests of pemmican, dried, shredded, or "beat" meat, preserved in fat in sacks of buffalo skin, with not quite all the hair left on the outside, it is said.

The Epic of Wheat.

In the early eighteen-seventies came an irruption of farmers into the plains; in the eighties Manitoba was pretty well filled up, in the nineties Saskatchewan and Alberta; and since that time settlement has pushed into

the remaining corners, and northward. Rifle and hunting knife gave place to plough and reaper, and the prairies blossomed into wheat.

The great Epic of Wheat has been only partly written: the high hopes of the early settlers; the killing frosts that changed promising crops into black ruins; the conquest of frost by the developing of earlier ripening varieties, and by the changes in temperature when large areas of land were broken; the triumph of "Marquis" wheat; the tragedies of hail and drought and flood; the tragedies of rust; the conquest of rust now almost within sight; the difficulties of transportation becoming better and better solved; the problems of markets and marketing very far from solution still; the dangers of one-crop farming, the spread of weeds, the development of mixed farming, the first tentative trial of wheat along merely the very edge of the forty-ninth parallel, and its spread almost to the Arctic Circle. Great will be the Epic of Wheat when some one is found to write it.

The New North.

A change is coming over the prairies. Manitoba and Saskatchewan have mines and mining in the north, and even lumbering and paper making. Saskatchewan in the south has beds of lignite coal. Alberta has coal of all varieties, natural gas, and oil. In the north can be seen the "last agricultural West" in the Peace River Valley, tar sands and oil along the Mackenzie, and growing herds of more or less domesticated buffalo and reindeer in the sub-Arctics.

The Glory of the Fields.

For visitors and adventurers from the homeland the supreme sight in the prairie provinces is the harvest—the farmer would add "when good." Even from train windows there are miles upon miles of golden grain. Years ago one of the best sights was the groups of stacks, but stacks are now scarcely ever seen. Then the fields of stooks were most attractive, but now they too are passing as harvesting methods change. The early Red River settlers reaped their fields and threshed their grain pretty much with the implements of Boaz and Ruth. Now the fashion is to cut and thresh with one rather cumbersome "combined" machine. But even machinery has not taken all poetry from the waves of shadow and of tossing heads that follow one another across the fields when the prairie breeze bloweth as it listeth.

A Sea of Mountains.

The backbone and "Great Divide" of the Continent, the grey granite, snow-capped Rocky Mountains, are taken as the boundary between Alberta and British Columbia—that is, between the Canada of the prairies and the Canada of the Pacific slope. On the prairie side they rise abruptly. One of the experiences of approaching them thus from the eastward is of snow-caps peeping one by one above the prairie horizon until suddenly the whole sheer wall stands glistening in the morning sun. On the western side, between the Rockies and the coast, several parallel ranges, the Selkirks, Gold Range, Coast Range, and others, stand like the thick-set ridges of a ploughed field, with deep-furrowed valleys between. These outer ranges are on the whole less grim and more green, more pleasing and less awe-inspiring than the cloud-robed Rockies.

Altogether, British Columbia has perhaps a hundred thousand square miles of mountain and valley, dotted with snow-caps, many still virgin peaks. It has miles upon miles, hundreds of miles, of glaciers, great rivers, and countless smaller streams, with rapids and waterfalls innumerable, immense water-power potentialities, a score of lakes that rival Switzerland's best, tens of thousands of green glades and many fertile valleys. In short, here are several various Switzerlands in one, only half explored, and with adventures enough to last the most eager for a hundred years. Fjords almost beyond counting, and as fine as Norway's, run like fingers of green water between blue bluff headlands of mountain and wood. Rivers and shore waters teem with fish. In the wombs of the mountains are copper, silver, gold, lead, and abundant coal. Valleys of deep volcanic ash are covered with orchards that, like Eden, bear every manner of fruit after his kind, irrigated by streams from surrounding glacial fields.

"The Coast."

Especially since the opening of the Panama Canal, through trade, even of prairie wheat, has developed. Vancouver and Victoria are Canada's outposts towards the Orient, thinking Pacifically, as Halifax and St. John, Quebec and Montreal think Atlantically. With a mild and pleasant coast climate, in which English holly grows and English accents and customs flourish—with all her wealth and all her beauty—surely the west coast of Canada must have had a very generous fairy godmother.

It was in 1793, four years after he had followed the great river that bears his name, to the Arctic, that Alexander Mackenzie pushed through with infinite toil from the prairies to the salt waters of the Pacific. Later, in a London drawing room, comparing notes with Captain Vancouver, he found that, one from the land, the other from the sea, they had been within a mere day of meeting in that same west coast inlet.

Some of the adventurers of 1930 will look out from observation cars on the seething waters that bear the names of the great geographer David Thompson, and of bold Simon Fraser—the Thompson and Fraser rivers. You may have pointed out to you some traces still of a mere ledge half-way up the precipice which in the fifties and sixties was the gold seekers' road to the adventurous Cariboo. Even camels, it is said, were tried on this dizzy trail. It was to the Cariboo that Viscount Milton and Doctor Cheadle made their "North-West passage by land" by way of Fort Garry, now Winnipeg.

With all her lure of beauty and of latent wealth as well, is it surprising that Scotsmen should have attempted an early Gretna Green marriage with this gifted heiress, and given her a name she acknowledged gracefully for half a century, New Caledonia? What with a New Caledonia on the west coast, and a Nova Scotia on the east, might not some suspicion arise of a deep, dark plot to make the whole of Canada a new domain for the Scot? Is there not even some suspicion that the plot succeeded?

Down by the Sea.

After the whole tour from east to west and back again, if there is one bit of Canada that could still present fresh charm, and not an anti-climax, even after the Province of the Western Coast, it is the Canada of the Atlantic, the provinces of Nova Scotia, New Brunswick, and Prince Edward Island.

Here some of the earliest settlements were made, by French and British, by Celtic Breton and by Celtic Scot. Indeed, here may have been the very earliest settlement of all, Vinland the Good of Lief Erieson and his followers. Here, around the battlements of Louisbourg, the two races, that later welded to make Canada, clashed again and again in the struggle for mastery. Here is the land of fair Evangeline, and here on many a quiet homestead may still be seen the ox-cart of the habitant, little changed in all the intervening years.

Nova Scotia, it may not be generally known, has a colony in the heart of *Auld Scotia—the parade, indeed*, at Edinburgh Castle. This became Novia Scotian soil many years ago, so that a noble lord might claim a new-land title, without the toils and perils of leaving the old country. The three provinces have in reality many colonies. Wherever in west or south some very big work is being done, Nova Scotians, New Brunswickers, or Prince Edward Islanders are, as likely as not, at the bottom of it. And half the universities of the continent have colonies of "the Maritimes" of Canada in their professorial staffs. The unusual brain and brawn may not unlikely have something to do with an early diet of herring and the shorter catechism. The Maritime people take naturally to education and politics, but sixty years of partnership in the confederation has scarcely accustomed them to be called Canadians. It was down by the sea in Windsor, Nova Scotia, that the peculiar humour of this new continent was born in the works of Judge Haliburton, whose Sam Slick is even supposed to have suggested Sam Weller.

One of the sights of all Canada is the Annapolis Valley at apple-blossom time; another, the fishing schooner *Bluenose* at a racing angle. Still another is the north-west arm of Halifax Harbour; another, the Bras d'Or

Lakes, which may have been the very region of Vinland itself. Another is the sixty-foot tide that rushes up the Bay of Fundy, roars around the base of Blomidon, creates a reversible fall at the mouth of the St. John River, and carries a tidal bore up as far as Moncton.

About the Maritimes much more could be said that would still leave more than all unsaid. Suffice it to say that here the adventurers of 1930 are to have their farewell visit, their last impressions, perhaps their best impressions, their stirrup cup, "Bon voyage!" and "Will ye no come back again?"

D. A. STEWART.

Scotland.

Presentation to the Scottish Committee of the British Medical Association.

DR. G. A. ALLAN, chairman of the Scottish Committee, has presented a mallet and stand for use on the chairman's desk at the Scottish House of the British Medical Association in Edinburgh. The gift is fashioned out of oak taken from the lining of the well shaft of the ancient Bishop's Castle at Glasgow. Dr. Allan, in making the presentation at a recent meeting of the committee, said that during the rebuilding in 1911 of the south-west wing of the Glasgow Royal Infirmary, which is on the site formerly occupied by the castle, the old well was exposed; a shaft was revealed, ten feet deep, which had previously contained spring water, but had been drained and covered in during some earlier alterations. The shaft was lined with black oak, one inch in thickness, and had stout square corner uprights of the same material. The wood was removed, and one of the workmen, thinking it might be of interest, offered a portion of a corner upright to his doctor, Dr. J. G. McCutcheon, also a member of the Scottish Committee, who (said Dr. Allan) in spite of fuel scarcity occasioned by coal and transport strikes and the great war, had preserved it. When the making of a mallet was mooted Dr. McCutcheon generously offered it for the purpose. Dr. Allan gave some account of the history of Glasgow Castle, with which in future the maintenance of order at meetings at Drumsheugh Gardens would thus be linked. The castle was occupied from the thirteenth century until the Reformation by a succession of bishops of Glasgow, who all, no doubt, quenched their thirst with water which had been carried up this old oak shaft. The castle had now vanished, but at one time it was a place of great strength, with battlemented walls and bastion. It was many times besieged in the sixteenth century, but following the Reformation it fell on evil days, and for a period was used as a prison, at one time confining 300 Jacobites. In the middle of the eighteenth century, in spite of repeated protests against the vandalism, permission was given for its stones to be used for the building of an inn in Gallowgate; before the century closed the ground on which the castle had stood, which had reverted to the Crown at the Reformation, was granted to the town for the building of the Royal Infirmary. From time to time during work at the Infirmary relics of the substructure had been revealed, including traces of the drawbridge and moat. The mallet, which is in the form of the old Scottish mason's "mell," bears a silver plate recording the fact of the presentation; on the stand is an inscription stating that the wood was obtained from the lining of the well at Bishop's Castle, Glasgow. On the motion of Dr. Buist, the committee recorded its grateful appreciation of Dr. Allan's gift.

Gibson Memorial Lecture.

The George Alexander Gibson Memorial Lecture was delivered at the Royal College of Physicians of Edinburgh on May 27th and 28th by Emeritus Professor William Sidney Thayer, late of Johns Hopkins University, Baltimore. Dr. R. A. Fleming, vice-president of the College, presided. The lecture consisted of an analysis of about 400 cases of acute endocarditis which had come under the observation of Professor Thayer and his colleagues in the Johns Hopkins Hospital. He pointed out that the chief incidence of rheumatic endocarditis, which was speedily fatal, occurred in the first decade of life. Endocarditis of a rheumatic nature might be caused by organisms of the streptococcal group, but these organisms were not found in numbers at the site of the lesions as in other definitely bacterial cases. It was possible that this type of endocarditis was due to a special sensitiveness of the endocardium, among certain individuals, to toxic products in the circulation. Of the definitely bacterial cases, more than 80 per cent. were due to non-haemolytic streptococci.

Royal College of Physicians of Edinburgh.

As intimated in the *British Medical Journal* of May 17th (p. 932), the Royal College of Physicians will celebrate the two hundred and fiftieth anniversary of its foundation on St. Andrew's Day, 1931. During the seventeenth century there was no proper medical school in Edinburgh, although the Incorporation of Surgeons had been giving anatomical demonstrations to its members and apprentices since its foundation in 1505. Attempts were made at various times under James I, Charles I, and Oliver Cromwell to obtain a charter for the foundation of a College of Physicians to regulate medical practice in the city, but these met with so much opposition from the universities, the surgeon-apothecaries, and others, that every scheme fell through, until in 1681 Dr. Robert Sibbald and some of his friends made a more determined effort. Sibbald tells in his interesting autobiography how the principal physicians in Edinburgh, having been consulted regarding a dispute between the surgeons and the apothecaries, held several meetings, and again proposed the scheme for establishing a college. Soon afterwards James, Duke of York, came to Scotland, accompanied by Sir Charles Scarborough, who promised to assist the Edinburgh physicians by using his influence with the Duke and with King Charles; the influence of the Earl of Perth with the Scottish nobility was also secured in favour of the scheme. Dr. Sibbald was fortunate enough to discover a warrant issued by King James I in 1621 directing the Scottish Parliament to introduce an Act for the establishment of a College of Physicians. This he showed to the Duke of York, who, on recognizing his grandfather's handwriting, said that he would see the business done. He seems to have acted with much vigour, and after some concessions had been made to the surgeons, the town council, the universities, and other opponents, the Duke sent up a draft charter to London, which was returned signed by the King. The next day, as Sibbald says, he turned it into Latin, had it written out on parchment and sealed with the Great Seal on November 29th, 1681, being St. Andrew's Day. He adds plaintively: "It cost a great deal of money to defray the charges of the plea, and for getting it signed at court, and sealed here." The patent was granted to twenty-one original Fellows of the College, whose names are mentioned. The town council followed four years later by appointing three of these Fellows—Sir Robert Sibbald (who by this time had been knighted), Archibald Pitcairne, and James Halket—to be professors of medicine, although there is no evidence that they actually held classes in this subject. The College was an active body from the first, and soon set about the formation of a library, the issue of a pharmacopoeia, and, what was much needed in those days at Edinburgh, the establishment of a public bath. In 1781 the College celebrated its centenary by the inauguration of a hall at the east end of George Street, Edinburgh, of which the foundation stone had been laid in 1775 by the celebrated Dr. William Cullen, then president of the College. The present hall was occupied in 1846. In consequence of legislative changes introduced by the Medical Act of 1858, the provisions of the charter granted by Charles II became obsolete, and the College was invested in its present rights and privileges by a new charter granted in 1861. In 1726 the College of Physicians began to collect subscriptions for building an infirmary for the sick poor, which the Fellows bound themselves to attend without salary, and in 1729 they opened a small hospital of six beds at Robertson's Close. This was the beginning of the Royal Infirmary of Edinburgh, which, at later dates, when the Infirmary moved to new buildings or crises arose in its affairs, received generous donations from the College. The post of physician to the Royal Infirmary has now become a privilege which is open only to Fellows of this College,

and many of them have expressed the opinion that the best method of celebrating the two hundred and fiftieth anniversary would be to contribute a generous donation to the appeal which has been launched by the managers of the Royal Infirmary in connexion with the bicentenary of this institution, referred to in these columns on May 24th (p. 971). There will probably be a banquet or other social function at the College of Physicians on St. Andrew's Day, 1931, but this must necessarily be restricted by the fact that the more important centenary of the charter of 1861 falls to be celebrated within thirty years.

Queen's District Nurses in Scotland.

The wife of the Lord High Commissioner paid a visit on May 25th to the Scottish Branch of the Queen's Institute of District Nursing in Edinburgh. Mrs. George Kerr, joint honorary treasurer of the Scottish branch, who received Her Grace, reminded her that the institute had been founded by Queen Victoria with money collected for her jubilee by the women of Great Britain and Ireland. The aim of the organization was to establish a complete nursing service throughout Scotland. There were now about 800 nurses scattered over the country from Wigtown to Shetland, in the Western Isles, and even in St Kilda. All the nurses had a complete training in maternity, infant welfare, and in the modern schemes of preventive medicine, for the council of the institute deprecated different nurses visiting the homes of the people. Nurses received a special training for six to eleven months in the home of the institute, because they often had to go into homes where the hospital appliances to which they had been accustomed were not available.

Glasgow Royal Hospital for Sick Children.

At the forty-seventh annual meeting of the governors of the Royal Hospital for Sick Children, held recently in Glasgow, Lord Provost Kelly, who presided, referred to the extensions that are being made to the country branch at Drumchapel. These consist of three main wards, two isolation wards, a nurses' home, and administrative departments. All the buildings, with the exception of the nurses' home, are of the bungalow type. A large verandah is attached to each ward, so that the patients will live, as far as possible, in the open air. The extended branch, which will accommodate about eighty patients, is expected to require an additional annual income of £3,000. The chairman also referred to the Children's Tintoil League, which has contributed £2,130 to the funds of the hospital by the sale of its collections from 1926 to 1929. The league is managed by a council, which includes representatives of the hospital and of numerous juvenile organizations in the west and centre of Scotland. Appeals were made by Dr. E. T. Roberts, late medical officer to the Glasgow Education Authority, for an increase in annual subscriptions, and for contributions to the research fund of £20,000 to enable the resources of the hospital to be utilized in the study and prevention of diseases of infancy and childhood. About 20,000 children, he said, under 5 years of age joined the Glasgow schools every year. Of these, 85 per cent. had decayed teeth, 6 per cent. had rickets, 5 per cent. enlarged tonsils, and 2 per cent. had discharging ears. Treatment in these cases was imperative. A research fund would assist the investigation of the causes of these disastrous conditions. In a special plea for this fund the directors refer to a circular, issued by the Scottish Health League, which estimates that the total sickness bill of Scotland is over £60,000,000 per annum. According to the annual report, the number of patients treated during the year in the wards of the hospital numbered 5,359, while the attendances of out-patients at the hospital and dispensary numbered 81,960. All the patients were under 13 years of age. The financial statement for 1929 shews an improvement on that of the previous year.

Edinburgh Royal Infirmary.

The Prince of Wales intends to pay a visit to the Royal Infirmary of Edinburgh on Thursday, June 12th, and to the Murray Home at Gilmerton, recently established for partially disabled soldiers, under the management of this institution. The annual flag day, which was held in aid of the funds of the Infirmary on May 24th, is expected to yield a total of £8,000, which may be exceeded when the returns from neighbouring country towns and districts have been received. The sum collected in the city itself was over £5,000. The endeavours of students, who held a carnival in the Waverley Market, resulted in a total of about £1,800, which is an increase of £500 on the amount raised by them last year.

Chancellor of Edinburgh University.

The election of a chancellor of Edinburgh University in succession to the late Earl of Balfour has resulted in the return of Sir James M. Barrie, Bt., O.M., by a majority of 1,940 votes over Lord Linlithgow. The number of voting papers sent out to graduates of the university was 13,602. Sir James Barrie is a graduate of Edinburgh University, and the impressions and experiences of his student life there are set down in his early book *An Edinburgh Eleven*.

England and Wales.

Winford Orthopaedic Hospital.

PRINCE GEORGE opened, on May 31st, a new orthopaedic hospital near Bristol for children suffering from various crippling diseases, including rheumatic lesions of the heart. Miss Town-end, chairman of the hospital committee, in a brief account of the objects of the new institution, said that, while it would be used mainly for Bristol children, patients from adjacent counties would be received to the limit of the accommodation. The best possible chance of permanent cure would be available for these children, since they would receive without delay the necessary early and continuous treatment. Sixty acres of land had been purchased, and there was thus ample space for enlargement, or for the subsequent erection of "country blocks" by other Bristol hospitals, if this was desired. At a future date, when funds permitted, it was proposed to erect two additional open-air wards, thus bringing the accommodation up to 160. The cost of the site, present buildings, and equipment was estimated at £64,000, of which £10,000 had been received from the funds of the old Orthopaedic Hospital, and £34,000 from donations; it was hoped that the outstanding amount of £20,000 would soon be forthcoming. The cost of maintenance of Bristol children of school age would be borne by the Bristol Education Committee, the Treasury making a grant of half the sum expended; parents would contribute according to their means. During their stay in hospital all the children would thus be able to receive such education as their physical strength allowed. Prince George delivered a short speech, commenting on the advantages offered by the new hospital, which he officially declared to be open. He then visited the wards and received purses on behalf of the building fund. The new Winford Orthopaedic Hospital possesses one large open pavilion divided into two wards, fronted by a broad concrete terrace on to which beds can be wheeled, and having a nurses' day room, kitchen, and bath-rooms attached. Here sixty children can be accommodated at once. There is a treatment block in close proximity to the wards, having operating theatre, plaster room, light room, and *x*-ray room, large hall for remedial exercises, and offices. The three-floor administrative block is capable of easy extension, having kitchens, stores, dining, day, and sitting rooms for matron and staff; rooms for house-surgeon and visiting medical staff; and twenty-nine bedrooms, each fitted with radiator, and with hot and cold water laid on. A large, well-equipped laundry has been fitted with electric washing apparatus. The boiler-house is capable of supplying heat and hot water for the whole institution, and of running the dynamos for electric light and current. There is a well, over 300 feet deep, with ample water supply, a pumping station, and a reservoir.

Housing Conditions in Liverpool.

At a recent meeting of the Royal Statistical Society an account was given by Mr. D. Caradog Jones, M.A., and Mr. Colin G. Clark, B.Sc., of the preliminary results of a scientific survey of present housing conditions among approximately 5,000 working-class families in Liverpool. This survey was stated to form part of a comprehensive survey of social conditions in Merseyside that is being

carried out by the Liverpool University School of Social Science. After describing the general configuration of Liverpool, whose population was estimated to be 873,000 in 1929, the investigators traced briefly the growth of congestion of industry and population in the central areas of the city. In the nineteenth century the rapidly increasing population had spread out into vast dreary deserts of houses with hardly an open space among them. These drab districts have hemmed in the centre of the city to a depth of two or three miles from the pierhead. In St. Anne's ward—"the plague spot of Liverpool"—42 per cent. of all the families visited were living four or more to a house. Every room in many of the larger houses was sublet to a separate family; the rooms were dark, dilapidated, and comfortless, lacking sanitary conveniences, taps, and sinks; and nearly every family had to depend for its cooking on an unsuitable bedroom firegrate. An instance was given of an eight-roomed house in this area with five bedrooms, two parlours, and a kitchen where six families shared a yard, one tap, and a single water closet. In seeking to determine a standard of overcrowding the investigators concluded that while the simple capacity scale of two persons to a room might serve a useful but limited purpose in marking the comparative progress in housing conditions (as used by the Registrar-General) it should no longer be countenanced by any authority, since shocking overcrowding occurred in spite of it. The general standard of family accommodation adopted for the purposes of the survey was equivalent to one room to two adults and one child if under 10 years of age. To guide the application of this standard the following rules were observed: (*a*) a separate bedroom shall be available for each married couple, which may be shared at most with two infants each under 5; (*b*) two adults of the same sex may also share a bedroom with two infants under 5; (*c*) with the exception of husband and wife no two persons of opposite sex who are both over 7 shall occupy the same bedroom; (*d*) not more than three persons over 10, or two persons over and two under 10, shall occupy one bedroom; (*e*) no bedroom shall be occupied by members of more than one family ("family" includes boarding lodgers). According to this standard overcrowding in the wards sampled by the investigators was found to be most frequent in tenements of two and three rooms. Preliminary examination of the problem on an economic basis suggested that varying rates of wages had much less effect than varying dependency and unemployment on the economic conditions of families. It was pointed out that the state of congestion revealed by the survey would have been much worse had it not been for the strenuous efforts shown by the municipal authorities in dealing with the problem. Over 80,000 people were now living in houses erected by the corporation since 1919, and approximately 15,000 had been rehoused in cottages and flats in the inner areas.

Jubilee of the Mental After-Care Association.

The jubilee of the Mental After-Care Association (Church House, Westminster) was celebrated at a meeting held at Drapers' Hall, London, on June 2nd. It is fifty years since the chaplain at a mental hospital, desiring to do something for patients after their discharge, won the sympathetic interest of Lord Shaftesbury and the help of some of the medical superintendents of the day. H.R.H. Prince George presided over a large gathering, and after remarking on the number of persons relieved—2,300 during the last year—said that the association's greatest asset was that it had no connexion with any Government department or local authority, with the result that the patient felt himself entirely free from any official atmosphere. Only lack of funds prevented expansion, but the association was not appealing in any special way for funds to mark its jubilee, only for a wider interest in its work and in the lot of the unfortunate people whom it set out to help. Lord Wakefield of Hythe, the president of the association, said that the work was increasingly successful. The gloom of centuries of superstition and misunderstanding had been responsible for many unsound but depressing conclusions in mental illness, and that gloom was being rapidly dispelled. Mental diseases were yielding all along the line to modern treatment, and the modern attitude was that mental illness was just an illness of a particular kind, and generally capable of both prevention and cure. Sir Maurice Craig, who has lately succeeded Dr. Percy Smith in the chairmanship of the council, said that the convalescent stage was important in all illness, but most important in mental disorder, because of the liability to relapse if re-adaptation to ordinary life was too difficult. He believed that no mental hospital had a convalescent hospital attached, but the association had a number of cottage homes comprising in all more than 200 beds—double the number available three years ago—with fully trained matrons and, in the larger homes, two or three other trained nurses. Another important branch of the work was finding employment for the discharged person; and here he reminded employers who shrank from the idea of taking on an ex-patient from a mental hospital that very many of these people were most sensitive and, once they were well, would render very conscientious and perhaps specially gifted service. Mr. L. G. Brock brought the good wishes of the Board of Control. There was no one in the community, he said, more in need of sympathy, and in general less likely to receive it, than the patient discharged from a mental hospital. This attitude towards the insane and ex-insane proceeded from a deep-seated fear of insanity; it was because of that fear and a desire to disguise its reality that the lunatic for generations had been made a figure of fun. The discharged patient from the asylum, terribly sensitive, nerve-shaken, and frightened, needed all the sympathy and help that could be given him. Mr. Brock said that he yielded to no one in his pride in the civil service, but he realized that there were very definite limits to what the administrative machine could provide. If human sympathy were something which could be obtained by filling up a printed form or making a statutory regulation it would be forthcoming in abundance, but it was because the help given by the association was unofficial that it had its crowning value. The problem of finding employment for persons discharged from mental hospitals was not merely that of finding a job for a man, but of finding a job which was going to give him the best chance of keeping well and of escaping from any relapse. The Mental Treatment Bill, now passing into law, had one provision which marked Parliament's recognition of the importance of the work which the association had done, for local authorities were empowered to subscribe to the funds of associations interested in after-care. The wording was necessarily indefinite, but that provision would never have been inserted had it not been for the work done by the Mental After-Care Association. He hoped that local authorities would take the fullest advantages of their new powers, and the association the fullest advantage of its new opportunities. Dr. Adeline Roberts related a few experiences of individual cases gained as chairman of the Mental Hospitals Committee of the London County Council, and the meeting then came to a conclusion. The report of the council of the association was handed to those present, but the main ground was covered in the speeches. The report mentioned that the association works in direct co-operation with ninety-four mental hospitals, or more than half the institutions in England and Wales, and the ideal is to establish active after-care work in connexion with every mental hospital in the British Isles.

National Institute for the Deaf.

The sixth annual meeting of the National Institute for the Deaf, which took place on May 30th at Church House, Westminster, was addressed by the Right. Hon. Stanley Baldwin, M.P., who, in appealing for public support for the Institute, remarked on the unconscious distinction made by the outside world in its treatment respectively of the blind and of the deaf. The blind, rightly, received every sympathy and consideration, but deafness, partial or complete, somehow failed to stir the imagination, although, said Mr. Baldwin, the isolation of the deaf was not less than the isolation of the blind, and it was not easy to say which was the greater calamity. Lord Charnwood, president of the Institute, said that the Minister of Health, in agreement with the Minister of Education, had decided to make inquiry through an experienced Government official into the conditions of the deaf and the possibility of relief. The matters to which inquiry might well be directed were the causes and

prevention of deafness, the education and training of the deaf in all stages of their career, their position industrially, and the openings for other forms of assistance. He also stated that the Institute had framed a scheme for a secondary school providing for the deaf the advantages which the ordinary secondary schools gave to normal pupils, and, further, it hoped to establish a centre of instruction in lip reading for the training of teachers as well as for the benefit of those who had lost or were losing their hearing. The report of the executive committee, which was submitted to the meeting, tells of much other useful research and ameliorative effort. Regional associations are being formed in various parts of England and in Scotland, with the object of compiling as complete a register as possible of the needy deaf in their areas, and of helping existing agencies or promoting new agencies for their welfare. These associations are working in the closest co-operation with the various local bodies which afford assistance, and whose independence the National Institute is anxious to preserve. The result of one task which the Institute has embarked upon will be, it is hoped, to save the deafened much expense and disappointment. It is compiling a list of dealers in artificial hearing devices who are prepared to give assurances of an adequate trial of any instrument sold by them, and of a fair arrangement as between vendor and purchaser if it does not produce satisfactory results. It may be added that the many-sided work of the Institute is done on an annual income of some £1,750.

Extension of the Homecroft Movement.

Dr. J. W. Scott of Cardiff University College, at a meeting of the National Homecroft Association held at Church House, Dean's Yard, Westminster, on May 22nd, recalled the services the late Dr. George Vivian Poore had rendered to rural housing and hygiene, and made an earnest appeal for further support for the Homecroft Memorial to him. The proposed teaching cottage, where the art of the semi-self-supporting garden home would be taught and Poore's hygienic and agricultural principles demonstrated, was related to the needs of English elementary education at the present moment. The Hadow Report on the education of the adolescent had opened a new prospect before the children, especially of the manual working classes, by proposing to raise the school-leaving age, and by recognizing the need for a break in the curriculum at the age of 11 or 12. But the committee had been careful to point out that no mere programme of "secondary education for all" did justice to their intention. It shone through the lines of the whole report that the desire was for a *different* secondary education. While more education was wanted, the committee was exercised over the question whether for children about to become miners and railway workers and agricultural labourers the subjects in the ordinary secondary school curriculum were the best introduction to the life that lay before them. Dr. Scott urged the adoption of a system, paralleled to a certain extent in Denmark, whereby the pupils in the new schools would spend one week in every three doing the practical work of home-building, under the conditions in which the tenants on the Homecroft Association's land near Cheltenham were now living—namely, in a workman's cottage, with a spare-time food croft attached, the croft being equipped to produce a considerable part of the family's daily food. Poore had everything to teach in connexion with that mode of living. The hope of the Homecroft Association was to erect a cottage to his memory, in which three relays of ten children each could be accommodated, under a teacher who was competent in both domestic science and food gardening, the boys learning the boy's part and the girls the girl's part in the organization of a healthy working-man's home. Town manual workers could live in the country, if they knew how to do it. The ten homecrofting families on the association's estate were now doing it. A memorial teaching cottage, erected beside the cottages and worked, if possible, in conjunction with the school authorities, would complete a concrete picture which would show more closely than anything else how the Hadow committee's ideals for a new kind of secondary education, which would be practical and suited to the direct needs of the less brilliant children, could be realized. Free gifts towards the memorial and share subscriptions for extension of the homecrofts may be sent direct to Dr. J. W. Scott, treasurer of the fund, University College, Cardiff.

Congress of the Royal Sanitary Institute.

The programme has now been issued for the forty-first congress of the Royal Sanitary Institute, which will be held at Margate from June 21st to 28th. Previous announcements about this congress have appeared in the issues of the *Journal* dated December 28th, 1929 (p. 1227), and May 10th, 1930 (p. 881). The business of the congress will be divided into the following six sections: preventive medicine, engineering and architecture, maternity and child welfare (including school hygiene), hygiene of food, hygiene in industry, and veterinary hygiene. Medical officers of health, engineers and surveyors, sanitary inspectors, health visitors, and representatives of sanitary authorities and of national health insurance services, will hold a series of seven conferences, the subjects of which will include maternal mortality, child welfare schemes, psittacosis, the school medical service, the health of industrial workers, slum clearance, inspection of foodstuffs, and town planning. Lord Cornwallis, president of the congress, will deliver his inaugural address on June 23rd at 3 o'clock, and on the same day at 5 p.m. the mayor of Margate will open the health exhibition which is being held in conjunction with the meeting. On June 24th at 8 p.m. Dr. O. Charnock Bradley, principal of the Royal (Dick) Veterinary College, Edinburgh, will deliver a lecture on diseases of domestic animals from the human angle.

India.

The Punjab System of Vaccination.

STEADY improvement is reported in the number of primary and secondary vaccinations in the Punjab during recent years. In his annual report for 1928–29 Lieut.-Colonel C. A. Gill, I.M.S., reports that the figures for 1926–27 showed a considerable increase over the average of the previous three years, while each of the two succeeding years has been characterized by still further progress in this respect. There remain, however, a relatively large number of unprotected adults in the Province, due to the decline of vaccination during the war and the period immediately succeeding it. Moreover, a large number of susceptible individuals have been added to the community by the high birth rate and the low infant death rate of the past three years. Further efforts are therefore necessary if the severity of future small-pox epidemics is to be reduced. A system is in force whereby the work of each vaccinator extends over the area controlled by one police station, but there is still a shortage of vaccinators calculated on this basis. In this respect the headquarters district of Lahore is notably behindhand, but it has to be remembered that the number of police areas in such a town district is based less on the size of its population than on the local prevalence of crime. It is possible, therefore, that in such centres as Lahore one vaccinator can successfully cope with the work in more than one of these areas. Vaccination work is less satisfactory in urban areas, and particularly in the smaller towns; the inhabitants here tend to neglect all precautions until an outbreak of small-pox brings home to them their individual danger. Educational measures are therefore highly desirable, and an indication of the too general ignorance is afforded by a case in which the parents of a student brought an action against the university for not permitting their son to remain in an examination hall when found to be suffering from small-pox.

Cholera in Bihar and Orissa.

A severe epidemic of cholera broke out during 1928 in the province of Bihar and Orissa. According to the public health report of that year it was not unexpected, as the disease had persisted through the winter months in several districts. Notwithstanding elaborate precautions by the Government and health authorities the rate of mortality rose from 1.4 in the previous year to 2.2, representing an increase of 28,000 deaths. Preventive measures in the

province include the maintenance of a permanent staff of ten doctors, who assist local organizations in dealing with epidemic disease. In addition to this special staff the Government maintains a reserve of one hundred vaccinators, who are also allocated to districts. In 1928 thirty doctors and over one hundred vaccinators were employed between April and October in various parts of the province. On the approach of the cholera season reserve supplies of kaolin and disinfectants are issued to civil surgeons. Kaolin, which is in general use, is regarded as an effective remedy; it is also convenient, because it does not deteriorate when stored, and is safely distributable. During 1928 local authorities were provided with cholera vaccine free of charge; over 241,000 doses were issued, compared with 5,000 in 1926. Some difficulty was anticipated in ensuring future supplies for free distribution throughout the province. All these preventive measures supplement the resources of the district boards, whose facilities appear to vary considerably. What seems to be mainly responsible for the serious outbreaks of cholera in the province are the large fairs and melas, which are attended by pilgrims from all parts of India. In June and July, when the Snen Jatra and Rath Jatra are celebrated at Puri, cholera is prevalent in the Orissa districts and in Bengal and Madras. During the celebration of these festivals in 1928 inoculation centres were opened at several railway stations, and six centres under six medical officers were established in the town itself. Over 25,000 pilgrims were inoculated, more than double the number of the previous year. Other melas held in the province were also visited by medical officers, who supervised the general sanitary arrangements and delivered lantern lectures on public health. The organization of lectures has become a regular part of the work of the publicity bureau. Since the Government withdrew its contributions towards the salaries of health officers most of the municipal authorities that employed them have dispensed with their services; only four of the large municipalities had health officers at the date of the report. This policy, which is deprecated by Lieut.-Colonel Phillips, I.M.S., Director of Public Health, is stated to have impaired the accuracy of vital statistics. Sanitary and health inspectors, however hard-working, are not regarded as sufficiently experienced or trained to check epidemic disease without the supervision of qualified officers.

Correspondence.

PREVENTION OF NOISE.

SIR,—Readers of the *British Medical Journal*, and especially those who have taken an interest in the subject of noise, will be pleased to know that a clause dealing with this has now been passed and incorporated in the Edinburgh Corporation Order Confirmation Act, 1930.

The clause is as follows:

34. (1) A noise nuisance shall be liable to be dealt with summarily in the manner provided in Part II of the Public Health (Scotland) Act, 1897, in the same way and to the same effect as in cases under Subsection (6) of Section 16 of that Act, and the Corporation shall have all the powers and duties with reference to a noise nuisance which a local authority has with reference to a nuisance under the said Act.

(2) For the purpose of this section a noise nuisance shall be deemed to exist where any person makes or continues or causes to be made or continued any excessive or unreasonable or unnecessary noise, and where such noise: (*a*) is injurious or dangerous to health, and (*b*) is capable of being prevented or mitigated, having due regard to all the circumstances of the case. Provided that if the noise is occasioned in the course of any trade, business or occupation, it shall be a good defence that the best practicable means of preventing or mitigating it, having regard to the cost, have been adopted.

(3) Nothing contained in this section shall apply to a railway company or their servants exercising statutory powers.

I have to tender my grateful thanks to the British Medical Association and the People's League of Health for the invaluable service they rendered by supporting the suggestion of making noise one of the nuisances liable to be dealt with by the machinery of local authorities, when this was first suggested.—I am, etc.,

Edinburgh, May 29th. THOS. G. NASMYTH.

STERILITY IN WOMAN.

SIR,—I have no wish to prolong this discussion beyond the bounds of usefulness, for I dealt in my previous letter (May 10th, p. 882) very fully with Dr. Leith Murray's remarks on certain details in my address. The matter is, however, of enough importance at the present time both to the lay public and to the profession to warrant some attempt on my part to clear up all matters left in doubt, and to summarize the opinions expressed.

First, everyone is agreed, I think, that there are many constitutional as well as local causes of sterility in woman, and that, with certain rare exceptions, occlusion of the tubes is produced by infections. Secondly, it is accepted that the husband is directly at fault in at least 15 to 20 per cent. of all infertile unions (excluding, I presume, those in which contraception has been practised). Mr. Kenneth Walker and others place the percentage of infertile husbands higher—one-third (33 per cent.) of all sterile marriages. Further, as I said in my last letter, husbands are indirectly, by infecting their wives, held to be responsible for about 40 per cent. of all cases of sterility in women. Clearly these are matters of considerable importance; and as Mr. Walker and I have said, in the face of them there is no social or scientific justification for not *insisting* that the husband shall be examined before tubal inflation or operative measures are practised on his wife. With this view Mr. Clare does not agree, and Dr. Leith Murray is not in more than abstract agreement for reasons he has explained. Further, I suppose we all concede that the hospital patient is entitled to as much consideration as the private patient. Yet Dr. Leith Murray doubts the possibility of testing the husbands of the poorer classes. He has not, however, tried to organize such an investigation. I have done so; and after the discussion on my address at Nottingham in reply to Mr. C. D. Lochrane I went fully into this matter. I am therefore at a loss to understand where Dr. Leith Murray discovered that "he [W. B. B.] now frankly admits that many of his hospital patients *are* so dealt with"—that is to say, that many of my hospital patients are subjected to tubal inflation without their husbands being first examined. I can only think that my statement that we have examined a considerable proportion of the husbands of hospital patients complaining of sterility without obvious cause led Dr. Leith Murray to the inference that in the remainder we practised tubal inflation on the wives. This has not been the case; indeed, it would have been contrary to our declared policy. The principle, therefore, should first be established; then, I am sure, it will be found possible to examine the husbands, in hospital as well as in private practice. We at any rate have encountered no difficulty; nor apparently has Mr. Kenneth Walker.

Thirdly, there is the question of technique. It seems that all are agreed that care must be taken to exclude the possibility of air leakage in the apparatus used. Further, while it is true that in my address, when speaking of radiographic examination, which appears never to be practised after air insufflation by some, I said this is often an unnecessary refinement—that is to say, although I have always had a radiographic examination made, I have *often* felt sure that the tubes were patent. While I stated that anyone experienced in the method is *usually* able to tell when air is passing into the peritoneal cavity, yet, as indicated by the words "often" and "usually," mistakes can be made—for example, with tubal spasm, about which much has been written by Meaker (1924) and others. So most will agree that we should deny no patient, hospital or private, the advantage of every scientific method of control at our disposal. For the inexperienced, as we all must be at first, radiography is, I think, indispensable.

Fourthly, we have to consider the statistical results of tubal inflation. The records of many experienced gynaecologists admittedly exhibit considerable variations; the tubes have been described as being patent in from about 40 to about 70 per cent. of all cases tested. This alone is indicative of the difficulty of finding the proper average percentage; possibly it lies somewhere between 40 and 70 per cent. My own worked out at 65 per cent. Dr. Leith Murray, however, has obtained a unique percentage (95) of patent tubes. I have therefore endeavoured to explore all possible sources

of error that might have led to such a high percentage of positive results. I certainly did not intend to say that all existed. Nevertheless, one small fallacy is clear: as the husbands were not, except in some private cases, examined, we should deduct 20 per cent. from his cases examined; but this does no more than bring his estimate down to 94 per cent. of positive results. The difference between this and my figure (65) may probably be explained, as I have endeavoured to show, if the much less exclusive selection of cases by Dr. Leith Murray be taken into account, together with the possibility that without radiography, a few errors in the estimation of positive results may have occurred. I know that my friend Dr. Leith Murray is as anxious as I am to discover the truth of the wide variations that exist not only between his figures and those of others, but also between those who have obtained a much lower percentage of positive results, as mentioned above.

Lastly, I would refer to the statement of Dr. Leith Murray that the underdeveloped adolescent uterus (often called the "*infantile uterus*" but really the pre-adolescent uterus) can be demonstrated by the passage of a sound. I would point out that in such uteri the *total length* of the cervical and uterine cavities may be normal, and often is. It is the ratio of cervical to uterine length that is important. This cannot accurately be discovered by the ordinary measurements made with the uterine sound, so far as I know. In spite of what Dr. Leith Murray says, I am sure the cochleate uterus may be, and not infrequently is, underdeveloped, as I have described and figured in other communications (*System of Gynaecology*, edited by Eden and Lockyer, 1917, i, 350. *Journ. Obstet. and Gynaecol. of the British Empire*, 1923, xxx, 138). There are, however, considerable differences of opinion as to the frequency of this condition. It seems to be more common in the North of England than elsewhere.

The following conclusions, as they appear to me, in regard to the matters under discussion, may be summarized as follows:

1. Tubal inflation is a valuable diagnostic method in selected cases.

2. This procedure should be controlled by radiography, for this makes for scientific accuracy.

3. The percentage of tubes found to be patent varies considerably. This may be due to the degree of accuracy secured, and to the methods of control practised in regard to the procedure employed, to the selection and variability of cases, and to the inclusion or exclusion of the state of the husband.

4. It is imperative, both for humane and scientific reasons, that the husband be examined.

—I am, etc.,

Liverpool, May 28th. W. BLAIR BELL.

TREATMENT OF ANGINA PECTORIS AND INTERMITTENT CLAUDICATION BY MUSCLE EXTRACT.

SIR,—I was much interested in the preliminary observations of Dr. M. S. Schwartzman (May 10th, p. 855) on this subject. In November last Dr. Szent Györgyi and I (*Journ. Physiol.*, 1929, lxviii, 213) recorded the isolation from muscle and other tissues of a substance which, from its chemical behaviour, we considered identical with adenylic acid. In addition to the several other reactions upon the whole animal that we reported we showed that it was a general arterial dilatant, including the coronary arteries. Subsequent work upon the rabbit's heart has shown that it is a most efficient coronary dilatant. It would be interesting to know if Dr. Schwartzman's extracts contain this substance, as the beneficial results reported by him might arise from increased arterial flow consequent upon the vessel dilatation produced by it. We also reported in our original paper that adenosine, prepared from yeast nucleic acid, had properties identical with those of muscle adenylic acid. Adenosine can be readily obtained in the pure state, and would allow accurate observations to be made upon one of the constituents of impure muscle extract, if it be shown that Dr. Schwartzman's extracts contain adenylic acid.—I am, etc.,

Department of Pathology, Cambridge, May 30th. A. N. DRURY.

DIAGNOSIS OF PLAGUE.

SIR,—It is not usually realized that in persons living in the Tropics acute swellings in different parts of the body may be manifestations of bubonic or septicaemic plague. On account of poverty and peculiar social conditions many of the patients seek advice at a very late stage of the disease, and occasionally they walk up to an out-patient department of a large hospital for the purpose of having what they think to be an abscess opened. A rapid pulse, fever, and constitutional symptoms are ascribed to the absorption of toxins from the abscess.

The unwary surgeon may open such abscesses; he may or may not find pus, and he is surprised that the patient either dies on the operation table or a few hours later in the wards. Such incidents are not uncommon in the Tropics. The swellings form in the neck, armpit, or groin, and when they are incised or punctured no pus is found. There is a certain amount of brownish exudate with necrotic material at the bottom of the swelling. Such cases are a real puzzle to the surgeon. They should not be operated upon, as they invariably prove fatal. The difficulty of diagnosis is increased when cases occur sporadically, and it is interesting to note that at surgical clinics plague cases turn up when one least thinks of them. When the constitutional symptoms are out of all proportion to the amount of toxaemia caused by the swelling, and when this phenomenon is coupled with a dry and furred tongue (so characteristic of all plague cases), plague is to be suspected.

The fact that such cases are missed offers a strong reason for an extensive clinical study of tropical diseases by every person who wishes to practise surgery in the Tropics.—I am, etc.,

J. DURLABH DHRUV,
Surgeon to Jamshedji Jijibhai Hospital, Bombay.

THE FAMILY INCIDENCE OF JUVENILE RHEUMATISM.

SIR,—In the interesting article on juvenile rheumatism by Dr. Gray Hill and Miss Mary Allan (May 24th, p. 949), there is a statement which I think might be qualified. It is pointed out that few of the brothers and sisters of rheumatic patients develop the disease, although living under the same conditions and having the same diet. The factors of housing, damp, clothing, are the same, and do not vary, but although the food on the table may be the same for all, it certainly does not follow that each and every one partakes of it in like proportions. In an article on heart disease in children (*Journal*, 1926, vol. ii, p. 684) I quoted a number of cases, and a reference to Cases 28 and 29 will serve to emphasize my statement. These two sisters disliked milk, were fond of vinegar, and suffered from chorea, while their only other sister drank milk, did not touch vinegar, and was quite healthy.—I am, etc.,

Swansea, May 27th. G. ARBOUR STEPHENS.

SPONTANEOUS SURGICAL EMPHYSEMA.

SIR,—It is certainly remarkable that Dr. F. Bedo Hobbs (May 24th, p. 950) should have seen two cases of the occurrence of surgical emphysema during labour within a week, but the condition is by no means unknown. A considerable number of references are given by Redfern in the *Lancet*, vol. i, 1890, p. 343: no fewer than three new cases are recorded in the *British Medical Journal*, vol. i, 1917; and in the *American Journal of Obstetrics and Gynecology*, vol. ii, 1927. Gordon reports two new cases and reviews 130 previously recorded.—I am, etc.,

Aberdeen, May 28th. BEATRIX B. LAW, M.D.

SIR,—I was interested in the two cases of surgical emphysema associated with labour recorded by Dr. F. Bedo Hobbs in the *British Medical Journal* of May 24th, as on May 4th I had a similar case, but could find no reference to the condition in the literature.

On May 3rd I was called to a cowman's wife, a vigorous girl of 22 in her first labour. It was a somewhat dry labour with a

left occipito-anterior presentation, and the patient worked very hard. Next morning, however, she was exhausted, and I made an easy forceps delivery. By the evening the patient had developed a surgical emphysema of the right side of the neck, with swelling of the right side of the face and a closed eye. This condition disappeared in a few days. The patient had a family history of tuberculosis, but there were no physical signs in her own chest, and the result of sputum examination was negative. On May 5th she developed a severe cough, but this disappeared in a few days.

I am, etc.,

HAROLD D. PICKLES, M.C., M.R.C.S., L.R.C.P.

Westerham, May 24th.

THE OLDEST MEDICAL ACT.

SIR,—Dr. J. A. Nixon twenty-five years ago gave some such name to the legislation of 1421, being led to it by the phrases of Robert Hare's Latin version in his *Archives of Cambridge, 1587*. As Dr. Parry has printed it in your issue of May 24th (p. 960), the legislation does seem rather obscure, but if we take up the *Rotuli Parliamentorum* (vol. iv, p. 158), we find among other *Petitions* presented in or to Parliament this very one beginning: "High and most mighty Prince" down to "convenient punishment." It is endorsed: "Reply to this petition is shown on the roll of this parliament, May 2, ninth year of Hen. V." This, then, was the demand, possibly passed by the Commons, sent up by medical reformers, such as Morstead and his military surgeons, who two years later got the Academy of Medicine started in London with the help of Gilbert Kymer and other physicians.

Now turning for the reply, or enactment, to the Rolls of Parliament for that year, on page 130 we get "The eleventh article, The Ordinance against intermeddlers in Fisik and Surgery." It begins: "Item to take away the mischiefs and dangers . . . be it Ordained by this parliament that the lords of the king's council shall have power from this same parliament to make suitable Ordinances, etc." This is clearly legislation by ordinance and not by statute. It directly omits the prayer in the petition for a "statute perpetually to be straitly used and kept," and gives an ordinance with the authority of Parliament instead. Great discussion has taken place on the difference. A statute was intended to have perpetuity, an ordinance was generally tentative. In 1340 a certain enactment was divided into two parts—one to be a statute for perpetuity and the other to be an ordinance—but both had full authority of Parliament and the King (see *Stubbs Const. Hist.*, vol. ii, pp. 584–586).

Thus I am afraid that the legislation does not constitute a statute law against him who "exerceat practicum in artibus medicinae et chirurgiae nisi prius fuerit approbatus in medicinâ apud universitates et in chirurgiâ apud magistros ejusdem artis." It is much to be wished that search be made for instances in the Patent Rolls of council ordinances against quacks before the great Act of 1511. I have tried to show (*Early History of Surgery*) that even before 1421 they could be sometimes arrested at the suit of the surgical town guilds, but in the country districts there was no check.—I am, etc.,

GEORGE PARKER.

Clifton, May 26th

ASYLUM MEDICAL OFFICERS.

SIR,—I have read with interest the letter by Dr. Power (May 17th, p. 928), from which it would appear that steps have been taken "to consider the status and conditions of service of asylum medical officers." It is indeed refreshing to think that our branch of the profession is receiving at least "consideration." I hope in the long run that we may receive something more tangible. Beyond the fact that the system appears to be under review, I do not find much that is helpful in Dr. Power's letter. The problem will have to be tackled in a different way if anomalies are to be removed and a tolerable state of affairs established.

In the first place I submit that the remuneration of an assistant medical officer is an insult to a professional man; £350 to £450 with emoluments is the average for those below the rank of deputy superintendent, and what are the conditions of service? His life is purely institutional. He lives in many instances within earshot of the patients. He sleeps on the premises. His holidays are a month in the year, and even that period has often to be taken at such time as suits the convenience of his superior officers. When he wants a week-end off he obtains it, not as a right, but as a concession which cannot be repeated too frequently. In the smaller asylums he generally lives by himself. There is little intellectual stimulus and no congenial society. The very people whom he serves—namely, the visiting committee—hardly know of his existence. He has no security of tenure, and he must, if indeed this be considered a disadvantage, take a vow of celibacy.

Of course someone will say that this state of affairs is purely temporary. In a short time the poor assistant will be duly rewarded and become a medical superintendent. We have but to think of the number of assistants and of the number of superintendents and this pleasing vision disappears. Someone else points to the assistant in general practice and tries to show that the asylum medical officer is in a much better position. There is no comparison possible. The assistant in general practice is often quite as well paid as the asylum medical officer, he has usually a definite understanding with his employer, and in two or three years he obtains a practice or a partnership. When he has obtained his practice or partnership, let his income be small or large, he has at least independence and freedom of action, without which no position is worth a straw.

If an inquiry is held into the status of asylum medical officers it must include a comparison of the salaries and conditions of service of all other officials, not only those in the asylums themselves but those employed in any capacity by county councils. It will include, of course, all the hordes of officials who under recent legislation have swooped down like locusts on the land. We hear a great deal about economy in local government administration, but this economy applies only to certain departments. If a list of officers in each county was prepared with their exact emoluments and qualifications it would be very illuminating reading for the general public.

My suggestions for improving the service are as follows:

1. For all entering the service there should be a three years' probationary period at a salary of about £400, with opportunity to obtain the diploma in psychological medicine. This diploma to be essential for the position of a permanent officer.

2. At the end of the probationary period he or she obtains charge of a department at a commencing salary of at least £600, with fixed scale of increments and a free house. The provision of a house some short distance from the main building, no matter whether the officer is married or single, to be obligatory.

3. Absolute responsibility for his or her department to rest on the officer in charge.

4. Abolition of the term "assistant." The officer would hold a position independent of everybody but the visiting committee.

5. The salary and status of the medical superintendent should be improved. He should exercise wide administrative and advisory powers, not only in his own institution but outside as well, with a view to co-ordinated action in dealing with mental diseases. Certain medical superintendents should be ex-officio members of the Board of Control. I consider Dr. Power's statement that administrative and scientific minds are disparate to be entirely wrong; I certainly have not found it so.

6. The establishment of properly equipped central laboratories for one or more counties. I have no faith whatever in the idea of a laboratory for each institution. Work of this kind must be carried out by highly trained experts. Such experts are not easy to find and should be still less easy to pay. They must receive adequate remuneration.

7. Absolute security of tenure for all officers during efficient service; a proper tribunal being set up to investigate all questions where an officer's position and reputation are at stake.

8. The provision of an adequate pension and a compulsory retiring age.

I consider these demands modest in the extreme. If granted in their entirety our position would still be much worse than that of the general practitioner. I have said

nothing of the position of deputy medical superintendent; his salary and status would approximate fairly closely to that of the medical superintendent; these positions would naturally form the goal to which able and energetic men could aspire. Dr. Power says "few men can afford to ignore completely the material side of life"; we can all agree with this. In the long run people are treated as they deserve. If our assistant medical officers are content with their position there is nothing more to be said; if they are not content they should be up and doing, for organized effort is all-powerful. I hope the British Medical Association will take a strong line of action in this matter.—I am, etc.,

May 27th. A.M.O.

SEQUELAE OF BRUCELLA ABORTUS INFECTION IN MAN.

SIR,—If Hardy, who is cited by Drs. E. Roland Williams and A. F. Sladden (May 10th p. 859), had lived among farmers and farm workers he might have been led to modify his statement that serious sequelae to Brucella infections are infrequent. According to Manson-Bahr[1] infection by *Brucella melitensis* is followed by

"such sequelae as abscess, orchitis, mastitis, parotitis, boils, etc. It is prone to give rise to ovarian pains dysmenorrhœa, amenorrhœa, menorrhagia, and to favour abortion and premature labour. In the male intermittent haemorrhages from the urethra are not uncommon. The germ may pass into the *foetus*: children born in such circumstances are weakly. Complications such as splenic and hepatic enlargement, enlargement of the mesenteric and cervical glands, suppuration, phlebitis, chorea, various psychoses, arteritis, endocarditis, melæna, haematuria, etc., are met with occasionally during the long course of this disease. After such a long debilitating illness the susceptibility to tuberculosis is much enhanced."

No one can say that any one or more of these is not to be found as a sequel of *Brucella abortus* infection in man. I have observed many of them in the case of a farmer who gives a history of an illness, always referred to as influenza, which he had five years ago. He is prematurely old and broken; his heart is damaged, and his respiratory passages are clogged with bronchitis and fugitive patches of pulmonary congestion; he has ulcers, phlebitis, extensive venous thrombosis (a common sequel). He suffers from distressing psychoses, and similar psychoses affect at least two members of his family—a fact which goes against the view that the cases are single and isolated. I have not been surprised to find during my residence in the country that cases of Brucella infection are numerous and widespread. How could it be otherwise when over 8 per cent. of mixed samples of milk have been found to contain *Brucella abortus*, and the danger has never been pointed out to those handling and milking cows, or to the milk consumer?

Only too often cases are diagnosed as influenza or a bad cold, the true diagnosis being revealed later by an examination of the blood. Thus the five cases reported in the *British Medical Journal* of May 10th presented such symptoms as flushing of the face with a definite blui-h tinge about the lips, patchy dullness of the lungs, fever and shivering, dark offensive motions, headache, backache, nausea, constipation, and oedema of the lungs. To anyone accustomed to seeing cases of *Brucella abortus* infection the peculiar and characteristic complexion, the state of the venous and digestive systems, and the result of treatment with an effective cholagogue are very informative. I would add that the farmer sternly hides the disease when it is present in his stock.—I am, etc.,

Harrogate, May 16th. R. CUNNINGHAM AFFLECK.

TREATMENT OF TUBERCULOUS KNEES.

SIR,—I was very pleased to read Mr. G. R. Girdlestone's criticism (May 24th, p. 977) on my treatment of tuberculous knees by the cautery. He asserts that my views date from the dark ages of tuberculosis. He is quite right: forty years ago we had to use our own experiences and go by external signs and histories, having none of the modern helps which one might put under a heading "Surgery made easy."

Chronic synovitis cases are very common; I have seen my share, have made the proper deductions, and have cured them without surgical intervention. Tuberculous knees in private practice are few and far between, I am glad to say; I have seen the differences and cannot recall a case in which I have been sorry I have delayed radical treatment. Mr. Girdlestone classes all my cases without reserve as chronic synovitis, which is absurd. He states that cases with both knees affected are rare, but that is no argument that those of my patients were not tuberculous; they do occur.

In my first case of double tuberculous knees the patient's mother died of phthisis; a few years previously her brother had both knees affected and also one finger. His knees were only treated with rest, strapping, blistering, etc.: we had not thought of the cautery then, and eventually I performed a double amputation and also removed his finger—he had already developed mischief in his lung. After amputation his case cleared up, and he became quite well; he married and lived for many years—in fact he died only last year. In the two cases amputated after use of the cautery, the bones were found profoundly affected; as Mr. Girdlestone remarks, the cases were sad, and ought to have been seen earlier in the course of the disease.

Mr. Girdlestone says positively that a tuberculous knee, treated with the cautery, moved after a fortnight, and used in walking about at the end of twelve weeks, will be worse—and he has had no experience of the treatment by cautery of tuberculous knees! What is the value of such an assertion? It is simply an exhibition of bias. I have far more faith in the description before and after treatment of our revered teacher, the late Mr. Jacobson of Guy's, who never failed to express his opinion, complimentary or otherwise.

My whole object in writing a description of my treatment was to prove a great shortening of the process of healing. I maintain that a tuberculous knee is very often primary; in cases where it is secondary treatment by the cautery would be contraindicated.—I am, etc.,

Wallington, May 30th. A. Z. C. CRESSY.

ETIOLOGY OF RHEUMATIC DISEASES.

SIR,—I was greatly interested in Dr. W. S. C. Copeman's article on the modern treatment of rheumatic diseases, in the *Journal* of May 24th (p. 942). In an article in the *Lancet* of May 12th, 1928, I made most of the points he mentioned, but he has not, I think, laid sufficient stress on the importance of assisting the excretory organs to eliminate toxins. I am convinced of the necessity of vaccine treatment, and, in cases where this has been tried and failed, I agree with Dr. Copeman that the failure has been due to the fact that the causal bacteria have not been isolated, or that the administration of the vaccine has been stopped too soon. The very fact that the patient has succumbed to the disease is *ipso facto* a proof of diminished defences against the bacterial invasion, and prolonged stimulation may be required before any antagonous increase in antibodies can be obtained. The more I see of these cases the more I am led to think that there is, in addition to any septic focus, some other necessary factor. A large number of my patients have noted their first symptoms of the onset within a month or two of a normal confinement. Careful search for a focus in the uterine body or cervix has revealed no sign of any infection. It is also well known that rheumatoid periarthritis is a fairly frequent concomitant with the menopause. These two observations lead one to think that some ovarian deficiency may be concerned in the production of the symptoms, and G. Riebold (*Münch. med. Woch.*, January 17th, 1930) has made the same observation. I am awaiting the production of some reliable ovarian extract with considerable hope.—I am, etc.,

London, W.1, June 2nd. L. C. DUNDAS IRVINE.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT has adjourned for the Whitsuntide recess. Before rising, the House of Commons discussed the surtax and income tax clauses of the Finance Bill, and also debated the London Naval Treaty. The Lords' amendments to the Coal Mines Bill were also due for consideration in the Commons.

The Parliamentary Medical Committee visited the Red Cross rheumatism clinic at Regent's Park on June 2nd. The next day the committee met at the House of Commons. Mr. Somerville Hastings, the honorary secretary, reported that the Minister of Health was prepared to receive a deputation from the committee after Whitsuntide to hear its arguments in favour of an advisory council on rheumatic clinics. At the same meeting the committee discussed the propriety of the dummy or test prescriptions which panel doctors are officially requested to send to pharmacists to test whether they are prescribing correctly. The committee decided that its chairman, Dr. Salter, should see the Minister of Health on the subject. A draft amendment was received from the British Medical Association as a suggested addition to the Road Traffic Bill. This ran:

"Where any payment is made by an authorized insurer under a policy issued under this part of this Act in respect of the death of or bodily injury to any person arising out of the use of a motor vehicle on a road, and the person who had so died or been bodily injured has to the knowledge of the authorized insurer received treatment from a registered medical practitioner elsewhere than in a hospital in respect of the fatal or other bodily injury so arising, there shall also be paid by the authorized insurer to such registered medical practitioner his reasonable fee for administering such treatment to an amount not exceeding one guinea for each person so treated."

The Medical Committee was of opinion that the tabling of such an amendment by medical members of Parliament would be undesirable, and it agreed that lay members of Parliament of all parties should be requested to sponsor it.

At the same meeting the Parliamentary Medical Committee was addressed by Sir Walter Fletcher, who spoke on the Medical Research Council and its organization. He pointed out that greater freedom in undertaking research was secured from the position of the Council, which was directly under the Privy Council, with the Lord President of the Council responsible to Parliament for its work.

Mental Treatment Bill.

PROCEEDINGS IN THE HOUSE OF LORDS.

On May 29th the House of Lords considered the amendments made by the House of Commons in the Mental Treatment Bill, a measure which had originated in the Lords. Earl RUSSELL, for the Government, said that most of the changes made by the Commons were purely drafting, and that only two or three deserved special attention.

Viscount BRENTFORD said he still took exception to one provision of the bill. This would for the first time allow voluntary patients to place themselves, without any certificate or reception order, in what used to be called a lunatic asylum. They could be placed there by their relations, again without any certificate. When a man had been sufficiently lacking in volition to place himself as a voluntary patient he could be detained there without being certified by any judicial body. He could even, if he recovered his sanity, or if he became capable of volition, still be kept there for twenty-eight days, although, *ex hypothesi*, quite sane again, and he could also, by order of the representatives of the Board of Control, be kept without any judicial decision for six months. The whole purpose of the bill was to do away with the ordinary certificate, which for a hundred years had been the safeguard of the subject in lunacy proceedings.

The House then agreed to almost all the Commons' amendments after brief explanations by Earl Russell. A slight change was made in the Commons' amendment which provided that:

The Board of Control shall upon the signed request of any person who considers himself to be unjustly detained under such application, recommendation, or order, furnish to him or to his authorized representative free of cost a copy of such application, recommendation, or order.

On the motion of Earl RUSSELL the words "or order" were deleted in both instances where they occurred in this amendment.

Discussion arose on the amendments made by the House of Commons to protect a person against proceedings brought for certification unless there is substantial ground for the contention that he acted in bad faith or without reasonable care. Earl RUSSELL said the changes made by the Commons strengthened the clause to some extent.

Viscount BRENTFORD remarked that the clause now applied not only to the medical profession but to anyone who had taken part in putting a patient into what was called a home. It covered anyone who applied for a reception order or had done any act with a view to signing or securing an order. The protection would apply to the patient's relatives.

Lord DANESFORT asked whether, when a man thought he was injured, there were precedents for compelling him to go to the High Court for leave to bring his action.

Lord DARLING said such a provision was on the Statute Book, and the courts had frequently acted on it. A tiresome class of half-crazed people suffered from an *idée fixe* which led them to bring actions against well-known people. They could be put on a list and not allowed to bring an action against anyone unless they satisfied the proper authority that they had a prima facie case.

Earl RUSSELL said no person with a genuine case would be stopped by this provision from starting proceedings. He pointed out that during the report stage of the bill in the House of Commons not a word had been said in opposition to this provision.

On the next amendment Earl RUSSELL remarked that the bill would not come into operation till January, 1931.

Earl RUSSELL then moved that the Lords agree with the new Clause 17, inserted by the House of Commons, to provide for an audit of the accounts of licensed houses. This clause ran:

(1) The licensees of every licensed house shall cause such accounts to be kept as the Board of Control from time to time prescribe, and the accounts so kept shall be audited once a year in such manner and by such person as the Board direct.

(2) A copy of the accounts and of the report of the auditor thereon shall be sent by the licensees to the Board of Control and the Board may, if they think fit, publish in their report the whole or any part of any such accounts or report, and any information obtained therefrom.

(3) The licensees shall pay to the auditor such fee in respect of the audit as the Board of Control direct.

Earl HALSBURY moved that the Lords disagree with this amendment. He said licensed houses should have proper supervision, but they were private ventures, and what excuse was there for saying that the accounts of a private venture should be examined? The Board of Control might order a very expensive audit, and could publish it in part while suppressing other parts. The clause had not been moved by the Government in the Commons.

Earl RUSSELL said that no concern which was officially allowed to have charge of a certified lunatic could be regarded as a purely private concern. The Government did not desire to deal with licensed houses in this bill, but the clause under discussion was pitchforked in with the support of Conservatives in the House of Commons. Although the Royal Commission had been equally divided on whether licensed houses should continue, it had agreed that if they did continue a power of this kind should exist. The Commission was driven to that conclusion by facts which came to its knowledge during its inquiry. No doubt if Mr. Greenwood had introduced a bill dealing with licensed houses he would have introduced this clause. The House must decide whether it should remain.

Viscount BRENTFORD said he did not know that any accusation was made against licensed houses on account of the amount of the fee or the mode in which they were run. Many were successful and well conducted. What was the advantage in the Government insisting that their accounts, which were private, should be submitted to the Board of Control and be published?

Earl RUSSELL said that in the Commons a statement was made that the services of district auditors would be used for this work, but Mr. Greenwood would agree that the public auditor should only nominally be appointed if it could be shown that a private audit had been carried out effectively. The audit was not proposed because of any question of the fees paid by the patient, but because a case came before the Commission where the superintendent of an important house of this kind was paid partly by commission on the profits, creating a direct conflict between interest and duty. There were also cases where extra articles had been supplied to patients at prices considerably in excess of their cost to the institution. He could not conceive that any portion of the accounts would be published after audit unless a definite public scandal required to be held up to odium and execration. Everyone in the Commons appeared to have agreed to the audit provision, which had been inserted at the instance of Sir Boyd Merriman.

Lord CARSON said he thought the real aim of the amendment was to put an end to licensed houses. It was one more attempt to get everything under the control of Government departments. He remembered defending three doctors who were all prosecuted for having what were called uncertified lunatics in their houses. All of them got off because the people were not lunatics at all. The truth of the matter was that the Board of Control thought the greatest benefit which could ensue to any subject was that he should come under its control. Do not let Parliament, under these pretexts, put an end to private homes, which, from his experience in the courts, he thought to be of great service.

The Lords then disagreed with the amendment by 31 to 17.

Other amendments were accepted, and the bill was returned to the Commons with a statement of the reason why the Lords disagreed with Clause 17.

Psycho-therapeutic Treatment.—Mr. CLYNES stated to Mr. Maunder, on May 29th, that no contribution towards the cost of psycho-therapeutic treatment, as distinct from observation and examination, of juvenile offenders was made from public funds. He knew of no power, under any Act, of the Home Office to make such assistance. In a reply to Mr Mander on the same day, Miss LAWRENCE said concentrated psycho-therapeutic treatment for persons with functional nervous disorders was available in the normal course for suitable cases at many institutions for the treatment of mental disorder, and the Mental Treatment Bill would facilitate further provision on these lines. She was unaware that one clinic in London which dealt with this type of patient had a waiting-list of between two and three hundred persons. In his question Mr. Mander alleged that this treatment could only be given by two or three clinics in the British Isles.

Food Poisoning and Food Preservatives.—Miss LAWRENCE stated, in a reply to Sir Walton Preston on May 29th, that it was the practice of the Ministry of Health to inquire into the causes of all food poisoning outbreaks of special interest, and the practice would continue. Since the Preservatives Regulations came into operation no cases had been reported which could be attributed to the prohibition of the use of preservatives. The boric acid formerly used was ineffective in preventing the development of food poisoning organisms. Asked whether she would inquire of the medical profession whether there was not a large increase of ptomaine poisoning, Miss Lawrence promised she would look into the matter. Miss Lawrence told Colonel Heneage and Sir Charles Cayzer, on May 29th, that there was no reason for prohibiting the importation of condensed machine-skimmed milk *in consequence of the recent death of a child at Grimsby*, which was alleged to be due to eating food made from machine-skimmed *condensed milk. Miss Lawrence said the medical witness at the* inquest on this child stated that it died from gastro-enteritis, which might have been set up by dirty food. Though the child was well nourished, its diet was injudicious. The machine-skimmed milk had been used in making milk puddings, and she had no evidence with regard to it.

Smoke Abatement.—Replying to Captain Peter Macdonald, Miss LAWRENCE said, on May 23th, that 112 local authorities had made by-laws under Section 2 of the Smoke Abatement Act, 1926. It was not thought necessary to require these by-laws to be made. On the same day Miss Lawrence told Mr. Somerville Hastings that it had not yet been found practicable to prepare, under *Section 5 of the same Act, a satisfactory by-law which would not* restrict heating and cooking to a few specified methods. Mr. *Greenwood had not received satisfactory suggestions from any* local authority or other body. Miss Lawrence was further asked by Mr. Somerville Hastings what technical difficulties prevented the Minister of Health from recommending the Ringelmann smoke chart for the purpose of determining when smoke from a factory chimney became a nuisance. Answering this, she said that, while the Ringelmann chart might be useful as a guide, it had not been considered sufficiently precise under everyday conditions of observation for inclusion in a by-law. Mr. Greenwood had reason to think that, in some places in the United States, the emission of smoke other than black might be an offence, as it could be in this country under the Act of 1926. *He did not consider* the issue of a model by-law dealing with other than black smoke *advisable until a satisfactory workable means had been devised* of observing the quality of such smoke. Though efforts had been made, that had not yet been found practicable.

Vivisection Films in Medical Schools.—Replying to Mr. Freeman, on May 29th, Mr. CLYNES said Section 3 of the Cruelty to Animals Act was qualified by a proviso that vivisection experiments might be made for the purpose of illustrating lectures in medical schools, hospitals, colleges, or elsewhere with a view to instruction in physiological knowledge, or knowledge which would be useful in saving life or alleviating suffering, on Certificate C being issued. Therefore he did not consider any action was necessary concerning a film shown publicly at the Professional Nursing, Midwifery, and Public Health Exhibition, which illustrated experiments performed under the authority of such a certificate.

Health of Shop Assistants.—At the meeting of the Select Committee on Shop Hours, on May 28th, Dr. T. H. C. Stephenson, statistical officer of the General Register Office for Births, Marriages, and Deaths, at Somerset House, gave evidence. Speaking of the incidence of illness among shop assistants, particularly in regard to phthisis, he said that sleeping in would certainly contribute towards this disease. There had, however, been a great improvement in this respect. Asked his opinion with regard to the use of alcohol by shopowners and assistants, he said that no occupation suffered from cirrhosis of the liver to the same degree as publicans, barmen, and cellarmen. Cirrhosis of the liver itself, however, did not indicate alcoholism. The committee adjourned until June 18th.

Appeals by Insured Persons to the Minister of Health.—On June 3rd Mr. GREENWOOD informed Mr. Rhys Davies that in 1927–28 there were 55 appeals under Section 90 of the National Health Insurance Act, 1924, to the Minister of Health by insured persons in respect of claims for sickness and disablement benefit, 20 being allowed and 35 disallowed. In 1928–29, out of 57 appeals, 25 were allowed and 32 disallowed; in 1929–30, out of 78 appeals, 22 were allowed and 50 disallowed.

Limitation of Output of Narcotics.—On June 2nd Dr. FREMANTLE asked the Home Secretary if he was taking steps to summon a preliminary conference of countries manufacturing narcotics with a view to limitation of their output, as suggested on behalf of Great Britain at Geneva on May 14th last, and if the Soviet Republic would be invited to participate in such a conference. Mr. SHORT, who replied, said the Home Secretary was not in a position to make any statement on the subject at *present*. Dr. FREMANTLE asked why, in view of the fact that the Foreign Secretary gave a definite promise at Geneva last month, there was this delay, and if the delay would soon be over. Mr. SHORT assured Dr. Fremantle that the question was under consideration.

Customs and Excise Notice.—On June 3rd Mr. SNOWDEN told Colonel Heneage that the Commissioners of Customs and Excise were advised that it was desirable to ensure that the contents of notice No. 37, Sec. 41.831/1929 were effectively brought to the notice of doctors. These were therefore either delivered personally, where this was practicable, or sent by registered post. Particulars of the numbers delivered by post and, in consequence, the cost of registration, could not be ascertained without undue labour.

Notes in Brief.

The Prime Minister states that the date of the introduction of the Factories Bill is still under consideration.

Mr. Clynes hopes to introduce legislation this autumn to amend the Children Act, 1908.

Obituary.

WE regret to announce the death, from angina pectoris, on Good Friday, of Dr. AUGUST SCHAUMBERG, president of the South-West Africa Branch of the British Medical Association. Dr. Schaumberg was 54 years of age, and was the senior practitioner in the South-West. He was born in Bavaria, and was a student at Halle and at Berlin, where he qualified as a dental surgeon as well as graduating in medicine and surgery. He settled in Windhoek in 1908. *During the war he served in the German Army Medical* Service in South-West Africa, and afterwards on the Western Front. In 1920 he returned to Windhoek, and was shortly afterwards appointed railway medical officer. A colleague ("L. H. B.") writes: Dr. Schaumberg was the *typical family doctor—kind, humorous, and sympathetic.* He was liked and respected by all sections of the community. We have lost a friend who always set a good example in his professional life. Dr. Schaumberg leaves a widow, two sons, and a daughter, to whom we offer our *deep sympathy.*

The death took place at his house in Esslemont Road, Edinburgh, on May 26th, of Dr. R. MACDONALD ROBERTSON, who had for many years carried on a large practice at Bruntsfield Place in that city, till his retirement some two years ago. Dr. Robertson graduated M.B., C.M. at Edinburgh in 1884, and proceeded M.D. in 1910. Shortly *after graduation he took up general practice in Edinburgh,* which he conducted for over forty years, being one of the best-known general practitioners in the city. For some years he was surgeon lieutenant to the Edinburgh City Artillery Volunteers, and as a member of the British Medical Association he took a great interest in the work of this organization.

The following well-known foreign medical men have recently died: Professor CHARLES WILLEMS of Liège, member of the Royal Academy of Medicine of Belgium, founder and president of the International Society of Surgery, honorary Fellow of the Royal College of Surgeons of England, and corresponding member of the Académie de Médecine of Paris; Professor CONRAD BIESALSKI of Berlin, an eminent orthopaedic surgeon, aged 61; and Dr. PATRICIO BORDBIO DIAZ, for forty-two years professor of children's diseases at Saragossa, and dean of the faculty of medicine, aged 74; Professor Dr. CARL LEINER, a eminent paediatrist of Vienna, aged 59; Dr. HOLGER MYGIND, for many years chief of the oto-laryngological clinic at the Copenhagen Municipal Hospital, and founder and first president of the Scandinavian Society for Oto-laryngology, aged 75; Professor DOMENICO LO MONACO, director of the Institute of Physiological Chemistry in the University of Rome; and Dr. JONES CARLTON, honorary president of the University of Missouri.

The Services.

HONORARY SURGEONS TO THE KING.

MAJOR-GENERAL H. Enson, C.B., C.M.G., C.B.E., D.S.O., and Lieut.-Colonel (temporary Colonel) G. De la Cour, O.B.E., R.A.M.C., have been appointed Honorary Surgeons to the King; the latter is promoted to the brevet rank of colonel.

I.M.S. DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London, on Wednesday, June 18th, at 7.15 p.m. Major-General F. G. H. Hutchinson, C.I.E., has been invited to take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Sir Thomas Carey Evans, *M.C.* (Major, ret.), 31, Wimpole Street, W.1.

DEATHS IN THE SERVICES.

Colonel Charles John O'Gorman, D.S.O., R.A.M.C. (ret.), of Warriston, Glenageary, died in a nursing home in Dublin on May 11th, aged 57. He was born at Buncraggy, Ennis, County Clare, on July 24th, 1872, the son of the late Thomas O'Gorman, was educated in the Catholic University, Dublin, and took the L.R.C.P. and S.I. in 1894. After filling the post of senior house-surgeon at the Mater Misericordiae Hospital in Dublin he entered the R.A.M.C. as surgeon lieutenant on January 28th, 1893, and is the last officer whose name is contained in Colonel Johnston's Roll of the Army Medical Service. He became lieutenant-colonel in the long war promotion list of March 1st, 1915, colonel on October 10th, 1922, and retired on October 10th, 1926. He served in the South African war of 1899–1902, when he took part in the defence of Kimberley, in operations in Cape Colony, in the Transvaal, and in the Orange River Colony, including the actions at Lindley and at Rhenoster River, was mentioned in dispatches in the *London Gazette* of May 8th, 1900, and April 16th, 1901, and received the Queen's and King's medals, with two clasps to each, and the D.S.O. After the war he was seconded for service with the South African Constabulary, from September 13th, 1902, to January 1st, 1905. During the war of 1914–18 he served in West Africa, India, and France, and was mentioned in dispatches in the *London Gazette* of June 30th, 1916, and March 7th, 1918. After the war he was appointed to the charge of the King George V Military Hospital, Dublin, and held that post up to the time of the treaty establishing the Irish Free State. He married Mary Josephine, daughter of Edward Davis of Clonshanville, Frenchpark, County Roscommon.

Lieut.-Colonel Arthur James Sturmer, Madras Medical Service (ret.), died at Clifton on May 11th, aged 79. He was born on February 1st, 1851, the son of Arthur James Sturmer of the Auditor-General's Office, Calcutta, was educated at Bart's, and took the M.R.C.S. and L.R.C.P.Lond. in 1874. Entering the I.M.S. as surgeon on March 31st, 1875, he became surgeon lieutenant-colonel after twenty years' service, was placed on the selected list for promotion on March 31st, 1901, and retired, with an extra compensation pension, on April 12th, 1905. He served in the Afghan war of 1879–80, and received the medal; and on the North-East Frontier of India in the Chin Hills expedition of 1892–93, gaining the frontier medal with a clasp. For some years before his retirement he held the posts of superintendent of the Government Maternity Hospital, Madras, and professor of midwifery in the Madras Medical College.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on May 31st the following medical degrees were conferred:

M.D.—L. S. Fry, L. P. L. Firman-Edwards, R. Hilton, J. V. Fiddian, B. E. Schlesinger.
M.B., B.CHIR.—C. Hill, G. E. Parker, J. E. Semple.
M.B.—J. C. C. Poole.

UNIVERSITY OF LONDON.

APPLICATIONS are invited for the Graham Scholarship in Pathology, value £300 per annum. It was founded under the will of the late Dr. Charles Graham to enable "a young man to continue his pathological researches and at the same time to secure his services to the school of advanced medical studies connected with University College Hospital as a teacher under the direction of the professor of pathology." Full particulars can be obtained from the Academic Registrar, University of London, S.W.7.

The degree of D.Sc. in physiology has been awarded to A. St. G. J. McC. Huggett of St. Thomas's Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following officers have been elected: President, Mr. Richard Atkinson Stoney; Vice-President, Mr. Frank Chetwoode Crawley; Secretary, Sir F. Conway Dwyer.

Medical News.

SIR EWEN J. MACLEAN, M.D., F.R.C.P., and Mr. ALFRED WILLIAM SHEEN, C.B., M.S., F.R.C.S., have been appointed Deputy Lieutenants for the county of Glamorgan.

THE House and Library of the Royal Society of Medicine will be closed to-day (Saturday, June 7th), and on Monday, June 9th.

THE summer dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, June 13th, at 7.45 p.m. for 8 p.m., with Mr. T. P. Dunhill in the chair. Sir Neville Howse, V.C., will be present as the official guest of the association. All medical visitors from Australia and New Zealand, whether members of the association or not, are invited to be present. The hon. secretaries are Mr. E. T. C. Milligan and Mr. Philip J. Jory (26, Queen Anne Street, W.1. Langham: 1579).

THE Cavendish Lecture before the West London Medico-Chirurgical Society will be delivered on Tuesday, June 17th, at 8.15 p.m., by Professor de Quervain of Bern, who has chosen as his subject "Cretinism and its relation to thyroid physiology." The lecture will be preceded by a reception at 7.45 p.m.

THE annual meeting of the Poor Law Medical Officers' Association will be held on Thursday, June 12th, at 6 p.m., in the Holborn Restaurant, and will be followed by an informal dinner (morning dress) at 7 p.m. Sir Arthur Newsholme will preside, and Professor Major Greenwood will introduce the subject of post-graduate education for the local government service. Any Poor Law or local government medical officer will be cordially welcomed, and may obtain full particulars from the honorary treasurer, Mr. F. Greenwood, Bank Chambers, High Street, Stoke Newington, N.16.

AN inaugural meeting of the Paddington Medical Society will be held on Tuesday next, June 10th, at the Town Hall, Paddington Green, W.2, at 9 p.m. The acting honorary secretary is Dr. J. Cohen, 23, Westbourne Park Road, W.2.

THE summer meeting of the Section of Laryngology of the Royal Society of Medicine will be held at No. 1, Wimpole Street, on Friday, June 20th, followed by the annual dinner at the Langham Hotel, Portland Place. The guests of the evening will be Dr. Logan Turner, Dr. J. S. Fraser, and Dr. Guthrie. The annual provincial meeting of the Section of Diseases of Children will take place at Norwich on Saturday, June 21st. The Section of Otology will hold its summer meeting at Nottingham on June 27th and 28th, when, in addition to papers, cases, and demonstrations, there will be a discussion on the proceedings of the Committee for the Consideration of Hearing Tests. A dining-car train will leave St. Pancras Station at 11 a.m. on June 27th, reaching Nottingham in time for the meeting at 2 p.m.

THE Fellowship of Medicine announces that the following special lectures in preparation for the M.R.C.P. examination will be given at the Medical Society of London, 11, Chandos Street, Cavendish Square, at 8.30 p.m.; on Tuesday, June 10th, Dr. H. Gardiner-Hill will describe recent work on the ductless glands; and on Friday, June 13th, Professor Hugh MacLean will deal with recent research on gastric physiology and pathology and its bearing on treatment. The subjects of special courses in June are as follows: gynaecology, June 16th to 28th, at the Chelsea Hospital for Women, occupying some mornings and/or some afternoons; dermatology, June 16th to 28th, at the Hospital for Diseases of the Skin, Blackfriars, each afternoon with special demonstrations on the two Tuesdays; medicine, surgery, and the specialties, June 16th to 28th, from 10.30 a.m. to 5.30 p.m., at the Prince of Wales's Hospital, Tottenham; proctology, June 30th to July 5th, at St. Mark's Hospital, City Road, occupying the whole of each day. Detailed syllabuses of all courses can be obtained on application to the secretary of the Fellowship, 1, Wimpole Street, W.1.

IN connexion with the ninth annual scientific session of the American Congress of Physical Therapy a post-graduate course in physical therapy will be held at St. Louis, Missouri, from September 8th to 12th inclusive. Full information may be obtained from the executive secretary, Suite 716, 30 N. Michigan Avenue, Chicago, Illinois.

H.R.H. THE DUKE OF CONNAUGHT, President of St. Thomas's Hospital, will distribute prizes to successful students of the Medical School on Thursday, June 26th, at 3 p.m., in the Governors' Hall. The whole hospital will be open for inspection during the afternoon.

THE summer meeting of the National Veterinary Medical Association will be held at the Royal Veterinary College, Camden Town, London, N.W., to-day (Friday, June 6th), at 2.30 p.m.

UNDER the auspices of the Central Association for Mental Welfare a course will be held in London, from August 30th to September 20th, in methods of teaching defectives collected in occupation centres and institutions, and with special reference to the low-grade types. Lectures will be given on mental deficiency, the study of the child and its development, and the evolution of speech in defectives. Classes will be arranged in occupational handicrafts suitable for young and adult defectives, and in rhythmic training. Visits will be paid to special centres, certified institutions, and occupation centres. The Board of Control has approved the course as being suitable for nurses and attendants in certified institutions and in mental hospitals, and for supervisors of occupation centres. Forms of application and further information may be obtained from the honorary secretary of the association, 24, Buckingham Palace Road, S.W.1.

THE Ministry of Health has issued a tabular summary of information furnished by local authorities in 1929 relating to the salaries and other conditions of service of women who are whole-time officers employed by them as health visitors, school nurses, tuberculosis visitors, and municipal midwives. In a circular letter accompanying the summary, which is addressed to local authorities, the Minister directs attention to the varying practices shown to exist in the employment of women public health officers carrying out similar duties, particularly to the wide variation in the salaries paid to health visitors, and to the lack of uniformity in the arrangements for the payment of their salaries during sick leave. The Minister expresses the opinion that local authorities which still pay inadequate salaries cannot expect to secure or retain the services of women properly qualified to perform the duties of health visitors, and he hopes that all local authorities will consider the desirability of adopting the practice of paying these officers full salary during sick leave.

ON his lecture tour in the United States Dr. Charles Singer is giving, among others, the following: The Hideyo Noguchi Lectures at Johns Hopkins University School of Medicine on "The Transition from Mediaeval to Modern Science"; the twenty-third Mary Scott Newbold Lecture at the College of Physicians, Philadelphia, entitled "Priests of Aesculapius and Sons of Aesculapius"; at the Cleveland Medical Library Association on "Anglo-Saxon Magic and Medicine"; at the Medical Society of the City and County of Denver on Pasteur; and in the Department of Zoology, University of California, two courses on the history of medicine and on historical and philosophical aspects of biology.

THE Organizing Committee of the recent conference on the giving of information on birth control by public health authorities (*British Medical Journal*, April 19th, p. 755) has published a report of the proceedings in pamphlet form. Copies (price 6d., including postage) can be obtained from the Conference Secretary, Parliament Mansions, Westminster, S.W.1.

DR. J. S. TAYLOR, assistant medical officer of health for Manchester, delivered last November at the Manchester College of Technology a lecture entitled "Smoke and health." This has now been published in pamphlet form, price 2d., and may be obtained from the joint committee of the Manchester and District Regional Smoke Abatement Committee and the National Smoke Abatement Society, Civic Buildings, 1, Mount Street, Manchester.

THE issue of *Nature* for May 31st contains the full text, with illustrations, of Professor G. Elliot Smith's Friday evening discourse, delivered at the Royal Institution on March 14th, entitled "New Light on Vision."

THE National Association for the Prevention of Tuberculosis has revised leaflets Nos. 3, 9, and 10, entitled respectively *Milk and Tuberculosis*, *Hints on the Management of Children up to 5 Years of Age*, and *Hints on the Care of Children of School Age*. The price of the leaflets is 1s. a dozen, there being a reduction on larger quantities. They may be obtained from the offices of the National Association, Tavistock House (North), W.C.1.

REBUILDING operations have already been commenced at the London Temperance Hospital. Four additional stories will be added to the out-patients' departments. The pathological and massage departments will be housed in quarters more commensurate with the importance of the work carried on therein. There will also be a new radiological department, lecture room, private wards for paying patients, and new nurses' quarters. The cost of rebuilding will be £15,000, towards which £11,000 is in hand or promised.

DR. FRIEDRICH VON MÜLLER, president of the German Academy and professor of internal medicine at Munich, has been made a doctor *honoris causa* of the medical faculty of Sofia University; and Professor Hacker of Graz, one of Billroth's pupils, has been made an honorary member of the German Society of Surgery.

A REUTER'S telegram announces that the Rockefeller Foundation intends to contribute £100,000 to provide laboratory facilities at Sydney University in the departments of surgery, pathology, bacteriology, and allied subjects.

THE fourth congress of the World League for Sexual Reform will be held in Vienna from September 13th to 20th. Particulars may be obtained from Dr. N. Haire, 127, Harley Street, W.1.

THE French national league against venereal diseases has offered two prizes of the value of 5,000 francs each for the best work on venereology. Three copies of the work, which must be typewritten in French, must be sent to the office of the league, 44, Rue de Lisbonne, Paris, VIIIe, by October 1st.

THE Italian Society of Laryngology, Otology, and Rhinology offers the Bilancioni prize, represented by the interest on 20,000 lire, for the best work on tuberculosis of the larynx, or at least tuberculosis of the organs within the domain of oto-rhino-laryngology. Competitors, who must be members of the society, should send their work to the president, Professor U. Calamida, by August, 1931.

LORD RAYLEIGH, D.Sc., F.R.S., will distribute the prizes at the London Hospital Medical College on Tuesday, June 24th, at 3 o'clock.

AN international tour for medical study to Turkey and Asia Minor will be undertaken by a group of medical practitioners, who will meet on August 20th at Bucarest, where they will visit the hospitals, and then make an excursion to the thermal baths at Sinaia. The journey will be continued via Constanza and the Black Sea to Constantinople, and thence to Angora. Further information can be obtained from Arzliche Auslandsstudienreisen, Biberstrasse 11, Vienna.

THE Prefect of the Seine has decided to give the name of Fernand Widal to a street recently opened in the 13th arrondissement of Paris.

DR. HANS SACHS, professor of immunology at Heidelberg, and Dr. Ernest Meinicke of Hagen, Westphalia, have been awarded the Ludwig-Darmstädter prize with the Paul Ehrlich medal.

PROFESSOR WILLIAM WELCH has been elected an honorary member of the Berlin Medical Society.

PROFESSOR VAQUEZ of Paris has been nominated for the Grand Cross of the Order of the Crown of Rumania.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963*, and *9964* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medicera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

PREVENTION OF SUNBURN.

DR. IVAN B. MCCANN (Leytonstone) asks for suggestions for the prevention of sunburn when climbing in Switzerland, especially above the snow line, during sunny weather. He wishes to know of the best application for the face, before exposure to the sun, to prevent scorching: "I suppose there is no lotion or pigment which would have a slight darkening effect on fair skin and thus protect it from sunburn, as a dark-complexioned person seems to be protected?"

MIDGE BITES.

"PERPLEXED" asks for information about any really reliable and practical prophylactic against midge bites. His wife is unable to go out of doors in the country in summer-time without suffering from immediate, and sometimes more serious remote, distress from the bite of these pests. They appear to single her out for attack and to have no difficulty in penetrating ordinary female attire.

FLEA INFESTATION.

"E. M." writes: I advise "Pulex" to sprinkle chlorinated lime freely on the floor, and after twenty-four hours have it washed, thus causing the lime to sink into the timber and cracks.

DR. F. S. D. HOGG (Rickmansworth) writes: I have known scrubbing floors and cracks between wainscots and floors with a strong solution of potassium permanganate to be very effective. The permanganate, of course, stains the boards.

TREATMENT OF PRURITUS ANI.

"CERONS" writes: Is a cure yet known for pruritus ani, a troublesome complaint which has now been worrying me for the past thirty years, on and off? I have tried numerous ointments and lotions, but all with no effect. The trouble arises from the semi-fluid discharge from the rectum coming into contact with the perianal skin and causing intolerable itching. A curious circumstance is that it only comes on when I am in bed and asleep, and this perhaps twice or thrice in the night.

INCOME TAX.

Theft of Instruments.

"G. B." explains that he has had the misfortune to lose his cases and instruments by theft. The inspector of taxes states that he cannot allow the full cost of replacement as a professional expense, but offers to allow £10 "as representing the normal annual cost of replacement.

*** We are of opinion that the full amount should be allowed. Apart from the obvious unfairness of refusing such an allowance, the cost of replacement of apparatus is, to the best of our knowledge, always allowed in such circumstances. If the local inspector is unable to allow the amount, we suggest that "G. B." should place the full facts before the Secretary, Inland Revenue, Somerset House, W.C.2, and ask that the allowance may be given to cover the entire cost of replacement—if not as a matter of law, at least as a matter of concession.

Purchase of Apparatus.

"J. G. H. S." asks whether he is entitled to a rebate for the purchase of apparatus used in his practice.

*** Nothing can be claimed for the original outlay for providing the apparatus; that represents capital expenditure. But the amounts expended from time to time on the repair and replacement of the apparatus are admissible.

Residence; Lease of Flat.

"W. P." has come to this country for a period not exceeding six months. He has had no residential relations with the United Kingdom in the past. He is taking over the lease of an unfurnished flat for eight months from midsummer of this year, but will, of course, be leaving before the lease expires—in fact, in October next. Do these circumstances involve him in liability to British income tax as an occasional resident here.

*** It has to be borne in mind that when a person has a residence here which is available for his occupation, normally liability attaches to him as a resident in the United Kingdom. We are not aware of any case on all fours with that quoted above, but a good deal would seem to turn on what is done with the flat during the four months to the end of February, 1931. If "W. P." sublets the flat for that period, so that it becomes unavailable for his own residence, we consider that he would not become liable as a British resident, but the result might very well be otherwise if, during that time, he retains his rights of occupation while the flat is used by his family or friends.

LETTERS, NOTES, ETC.

DANISH TREATMENT OF ITCH.

WE have received the following communication from Dr. W. H. MARTINDALE with reference to the correspondence under the above heading: In Dr. Alexander Cannon's letter (May 24th, p. 985) regarding the making of the polysulphide solution, which is a step in producing the ointment used in this treatment, reference is made to a communication from Dr. T. Douglas Ross in the *Journal* of February 15th (p. 320). Dr. Ross had difficulty in effecting solution, using 1 kilogram of 50 per cent. caustic potash, as originally mentioned by Dr. Cannon on January 25th (p. 143). I have made the solution, and the essence of the matter seems to be that 1 kilogram of 50 per cent. caustic potash solution is not enough for 1 kilogram of sulphur—in fact, I am inclined to think that the 1 kilogram is an error in transcription, because the formula given by Lomholt in the *Lancet* of December 18th, 1920 (p. 1251), distinctly specifies 2 kilograms, and I certainly find that nearly this amount is needed, producing a dark reddish-yellow liquid. A further point arises as to what has been regarded as a 50 per cent. solution of potash. The workers at Copenhagen no doubt used equal weights of potash and water, and this weight/weight solution was used in my preparation. A solution made up of 50 grams of potash with water to 100 c.cm., commonly understood as a 50 per cent. solution within the Empire, would be considerably weaker—only about 33 per cent. weight/weight.

THE BLOOD TRAIL.

DR. JOHN IVES (St. Mary's Hospital, W.2) writes: Shortly after reading Sir John Bland-Sutton's very interesting Ingleby Lecture (*Journal*, May 24th, p. 937) I came across the following, which makes another interesting link in the "Blood Trail." It is taken from Pepys's Diary for November 14th, 1666. "Dr. Croone told me that at a meeting at Gresham College to-night there was a pretty experiment of the blood of one dog let out (till he died) into the body of another on one side, while all his own run out on the other side. The first died upon the place, and the other very well, and likely to do well. This did give occasion to many pretty wishes, as of the blood of a Quaker to be let into an Archbishop, and such like; but, as Dr. Croone says, may, if it takes, be of mighty use to man's health, for the amending of bad blood by borrowing from a better body." Two days later Pepys is told that the dog "is very well, and like to be so as ever": he doubts not "its being found of great use to men." It is interesting to note that it took over two hundred years for this pious prophecy to be fulfilled—with safety.

THE TIMES OF OVULATION AND CONCEPTION.

"T. M. C." calls attention to statements in an article by K. Ogino in the *Zentralblatt für Gynäkologie*, of which an abstract appeared in the *Epitome* of May 10th (para. 434). Our correspondent writes: Ogino states that after the eleventh day *preceding* menstruation conception is impossible, and, on the other hand, that fruitful coitus takes place from the nineteenth to twelfth day *before* menstruation. Is there any general support for this theory among our British gynaecologists? Obviously, the theory has most important bearing upon birth control if true. On the other hand, if incorrect, as I think most physicians would imagine, the idea, if disseminated, may have very unsatisfactory results.

MEDICAL GOLF.

THE annual summer meeting of the Medical Golfing Society was held at Walton Heath on May 29th; more than 100 members competed, and all greatly enjoyed the kind hospitality once more extended to the society by Lord Riddell. The links were in grand condition and the weather was perfect. The various competitions resulted as follows:

Lancet Challenge Cup.—W. Rowley Bristow, after a tie with C. Max Page at 1 down.

Milsom Rees Challenge Cup.—M. G. Mayou, after a tie with J. W. Harrison at 5 down.

Henry Morris Challenge Cup.—A. Don, 3 up.

Veterans' Cup.—A. Don, 3 up; George Dawson, 2 up.

Class 1.—First prize: C. Max Page, after a tie with W. Rowley Bristow at 2 up. *Best last nine holes:* H. C. Apperley, 1 up

Class 2.—First prize: A. Don, 3 up; second prize: George Dawson, 2 up. *Best last nine holes:* J. W. Harrison, 3 up.

Foursomes.—1st, T. J. Kelleher and J. Grace; 2nd, Lindsay Rea and W. McCullagh.

WITH the links in a heavy condition owing to the recent rains, members of the Manchester and District Medical Golfers' Association found low scoring difficult on the Prestbury and Upton course on May 28th, when the annual 18-hole handicap meeting of the association was played. The best net return was 73, at which figure there was a tie between Dr. M. McGregor of Prestwich and Dr. A. B. S. Drysdale of Salford, who were left to make their [illegible] to a play-off to decide the destination of t[illegible] Dr. McGregor eventually won. Dr. A. [illegible] won the Walter gold medal for the best gross score with a round of 78, while the Walter silver medal for the best gross score by those with handicaps of 10 or over was won by Dr. Drysdale, who was round in 83. The leading returns were: Dr. M. McGregor and Dr. A. B. S. Drysdale, 73; Dr. D. G. Macpherson (Newton Heath), 74; Dr. A. Burns (Openshaw), 75; Dr. J. W. Chadwick (Bollington) and Dr. J. M. Cowan (Prestwich), 76; and Dr. H. M. Fort (Oldham), 77. There were nearly 140 competitors.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 74, 75, 76, 77, 78, 79, 82, and 83 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 80 and 81.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 255.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

510. The Clinical Syndrome of Hyperparathyroidism.

FOLLOWING his discovery of an active parathyroid hormone, Collip has summarized the effects of the experimental injection of an excess of this secretion. The essential characteristic is hypercalcaemia, sometimes exceeding 20 mg. per 100 c.cm. of serum. The symptoms are restlessness, respiratory distress, vomiting, diarrhoea, and, later, haematemesis and melaena, collapse, and death. Haematuria is usually present, and, in fatal cases, the kidneys cease to function. During this terminal period the phosphates and non-protein nitrogen of the blood rapidly increase, while the volume, density, and coagulation time of the blood are decreased. Post mortem, haemorrhages into the kidneys and walls of the stomach and small intestine are found. D. P. BARR and H. A. BULGER (*Amer. Journ. Med. Sci.*, April, 1930, p. 449), reporting five cases of hyperparathyroidism, state that the clinical symptoms of this condition are similar to those found experimentally. Hypercalcaemia is the most important diagnostic sign; though noted in a few other diseases, its presence usually indicates increased function of the parathyroid glands. Other symptoms are hypotonia and diminished electrical excitability of muscles, with decalcification of bones, and an abnormal excretion of calcium in the urine. In some cases nephrolithiasis and hypophosphataemia have been observed. Hyperplasia of the parathyroids and clinical evidence of hyperparathyroidism have been found in many cases of generalized bone disease, including rickets, puerperal osteomalacia, multiple myeloma, and carcinomatous metastases in bones. The parathyroid changes appear to be secondary to the osseous ones. While in some cases the increased parathyroid function may possibly be useful, in other cases it is actually harmful by increasing the decalcification of the bones. In generalized osteitis fibrosa cystica (Recklinghausen's disease) the clinical picture of hyperparathyroidism is most frequently encountered; it may possibly be primary, and is unquestionably harmful. In such cases removal of parathyroid tissue has brought about clinical improvement and apparent arrest of the bone disease. Determinations of the calcium and phosphate content of the serum should be made in all cases of generalized bone disease because of their therapeutic indications.

511. Carotinaemia and Diabetes.

IN a previous communication on the phenomenon of xanthosis occurring during the course of diabetes mellitus, I. M. RABINOWITCH (*Arch. Int. Med.*, April, 1930, p. 586) stated that its incidence was not great, and discussed its significance. He suggested that a diet high in vegetable content to which the diabetic patient is subjected, and to which this condition is generally attributed, is not the only factor involved. Its prognostic importance was indicated by the following observations: in the group of patients (diabetic) with the skin pigmentation due to this cause the number of those requiring insulin was high; the incidence of arterio-sclerosis was also high; moreover, hypercholesterolaemia was marked. Other features noted in certain cases were insulin oedema, hyperglycaemia difficult to control with insulin, and a raised renal threshold for sugar. It was suggested that xanthosis occurring during the course of diabetes mellitus was of unfavourable prognosis, and the present investigation was undertaken to test the correctness of this hypothesis. Samples of the blood of 500 diabetic patients were analysed for sugar, cholesterol, bilirubin (van den Bergh test), and carotene. Determinations were attempted of the different degrees of carotinaemia and their incidence, of the relationship possible between the sugar and carotene contents (which was found to be absent), and the possible relationship between the carotene and cholesterol contents; these substances were found to be related. Rabinowitch concludes that for some unknown reason certain diabetic patients apparently retain ingested vegetable pigments to a greater extent than others. The importance of this observation is that such persons usually do not appear to do well clinically, and the majority have a high blood cholesterol content. Though large amounts of carotene may be responsible for high values of plasma cholesterol because of their chemical relationship, this does not appear to be the only cause. In view of this relationship and of the unfavourable prognosis for patients with high cholesterol contents, it is suggested that marked carotinaemia also indicates an unfavourable prognosis. As occurs with cholesterol, there are exceptional cases in which carotene may accumulate rapidly in the blood and yet no downward progress be noted. Since cholesterol and carotene contents of the blood do not always run parallel to each other, two *different* factors are conceivably involved, though both probably operate in the majority of cases.

512 Macrococcal Cerebro-spinal Meningitis.

M. H. WEINBERG (*Journ. Nerv. and Ment. Dis.*, April, 1930, p. 412) reports a case of cerebro-spinal meningitis which presented several interesting clinical and bacteriological features. Though the onset of the disease was characteristic of cerebro-spinal meningitis, the patient was sufficiently ill to justify tuberculous meningitis being suspected, and encephalitis was also considered as a possibility. The high sodium chloride content in the cerebro-spinal fluid was the only consistent indication against tuberculosis. The diagnosis was ultimately settled by the isolation from the blood (on the sixth day of the disease) and from the cerebro-spinal fluid (five days later) of bacteria which have previously been described under the designation of giant cocci. As the patient grew progressively worse, despite the administration of antimeningococcal serum, a cisterna magna puncture was performed; about 15 c.cm. of very turbid fluid was withdrawn, and 10 c.cm. of antimeningococcal serum was given. Rapid recovery followed this procedure. Weinberg considers that the clinical evidence is sufficient to substantiate the giant coccus as the causative agent of the meningitis, and from the prompt recovery after the antimeningococcal serum treatment concludes that these cocci were of the meningococcus type. He believes that a watch for, and repeated examinations for, unusual organisms in this condition are indicated; he emphasizes the point that large quantities of serum are not necessary, and that successful treatment depends more on the ready accessibility of the serum to the disease focus.

513. Coronary Occlusion with Survival.

J. A. EVANS (*Minnesota Med.*, March, 1930, p. 163) remarks that the majority of patients die within a few months of the onset even if they survive the earlier stages of cardiac infarction. He has studied coronary thrombosis in its milder manifestations, and reports his observations on ten patients who have survived this illness; nine of them are still alive more than a year after the attack, and seven of them more than two years. In two instances the patient had experienced at least two occlusions and several attacks of angina pectoris. Survival in such cases is attributable either to the blocking of a small vessel or to the presence of good capillary anastomoses. In seven of the patients Pardee's sign appeared in the electro-cardiogram, this phenomenon being found within a few days, and lasting in some cases as long as two years. Auricular fibrillation, bundle branch block, and notching of the Q R S complexes were also observed. From a study of the history in these cases and the course of the disease the author infers that many patients survive minor occlusions, while rarely there is recovery from an extensive infarction. When death does not immediately follow coronary thrombosis it may occur months later from congestive myocardial failure, with or without further attacks of precordial pain.

Surgery.

514. Formation of True Bone in a Cystostomy Scar.

RELLAND and STAGNARO (*Bull. et. Mém. Soc. Nat. de Chir.*, April 5th, 1930, p. 454) report the case of a man, aged 63, who had had a suprapubic cystostomy performed for a stricture of the urethra. A suprapubic fistula persisted for some months, and was subsequently excised under a local anaesthetic. During the operation a small cylindrical piece of bone was found embedded in the scar and was removed. It was over 2 cm. long, and its hardness was between that of cartilage and bone. After the removal of this plaque of bone the suprapubic wound healed quickly, and the patient left hospital able to pass urine naturally. Cases of bone formation are more common in operations above the umbilicus, but other cases have been reported in chronic suprapubic fistulae following operations on the prostate. It has been noted that ossification occurs most frequently in secondarily infected fistulae, and therefore it is suggested that some form of irritation is a contributing factor to the formation of bone. The bone is usually of small size and the treatment must be

its complete excision with the surrounding tissues; the wound then heals easily and rapidly. The pathology of the condition is interesting as to whether the bone originates from the periosteum of the pubic bone or is in the nature of a myositis ossificans.

515. Mobility of the Caecum.

A. CROTTI (*Amer. Journ. of Obstet. and Gynecol.*, March, 1930, p. 356) remarks that the number of cases of definite chronic appendicitis is small compared with the number of right iliac fossa complaints. It has often been found in cases with a history of "chronic appendicitis" that the appendix is apparently normal at the operation, and the symptoms are unrelieved by its removal. There are, in addition, the unexplained left iliac fossa complaints that imitate the syndrome of the so-called chronic appendix. Crotti believes that the cause of these disturbances can in most cases be traced to developmental errors, mobility of the colon and caecum being congenital. Developmental anomalies result in colonic stasis. With alteration of the normal motility abnormalities of the secretion and absorption functions develop, with consequent putrefaction of the colonic contents and intestinal toxaemia. The pain is said to be due to the constriction of the colon at the brim of the pelvis. Systemic disturbances, such as headaches, neuroses, fatigue, and sallow skin, are quite commonly associated symptoms. An overloaded mobile colon pulls on the kidney, liver, pylorus, and gall-bladder, tending to general ptosis. Moreover, the superior mesenteric artery is put on the stretch by a sagging colon. The author considers that, although medical treatment may be palliative, the only permanent relief of the symptoms is surgical intervention, the colon and caecum being anchored to the split parietal peritoneum. No fatalities or complications occurred in the author's experience. The operation was well tolerated and the results were excellent, without exception.

516. Treatment of Varicose Ulcers.

I. DAINOW (*Ann. de Derm. et de Syph.*, March 30th, 1930, p. 271) reports 18 cases of varicose ulcer treated by injections of acetylcholine with success; 17 were cured in a short period, in no instance more than six weeks. All the patients were treated also with routine local applications, but when compared with cases treated with local applications only the results were not only considerably better but much quicker. The theoretical basis of the treatment depends on the power of the drug to cause vaso-dilatation, especially in the limbs. The drug is injected hypodermically in a 5 per cent. solution, 1 c.cm. being given daily. No ill effects or pain were observed, and there are said to be no contraindications to its use. The author refers briefly to the insulin and sympathectomy treatment of varicose ulcers.

517. Typhoid Empyema.

V. RAPANT (*Med. Klinik*, March 21st, 1930, p. 427), who records an illustrative case, states that while serous or sero-fibrinous pleurisy is one of the relatively frequent complications of typhoid fever, empyema is always a rare event. It is most frequently secondary to a serous or sero-haemorrhagic pleurisy, and only rarely develops as a primary purulent effusion. Rapant's patient was a man, aged 25, who in spite of the most careful clinical examination did not show any evidence of the empyema having been due to pneumonia, broncho-pneumonia, or a pulmonary infarct, nor was there any evidence of its being secondary to inflammatory processes in the ribs, rib cartilages, or typhoid abscess in the liver, spleen, muscles, or elsewhere. Repeated examinations of the duodenal secretion, the contents of the gall-bladder, urine, and stools, failed to show any indication of the patient being a typhoid carrier. Recovery followed drainage of the pleura by Bulau's method.

Therapeutics.

518. Antitoxin in Diphtheria.

V. BIE (*Ugeskrift for Laeger*, January 16th, 1930, p. 55) draws attention to the great differences in the diphtheria mortality and dosage of antitoxin in Denmark and Germany. In the latter country Professor Friedemann of the Rudolf Virchow Hospital in Berlin has recently pointed out that while the diphtheria mortality in this hospital formerly ranged between 4 and 8 per cent., it rose in 1926 to 13.2 per cent., and in 1927 to 16.3 per cent. In 1928 it was 11.6 per cent. The dosage of antitoxin usually given in Germany being comparatively low, the question was raised whether the comparatively high death rate from diphtheria in Germany might not be considerably reduced by the adoption of the system of massive dosage employed since 1920 by Bie at the Blegdam Hospital in Copenhagen, where the mortality from faucial diphtheria has kept uniform between 1 and 2 per cent. since 1920. Bie brings his arguments in favour of large doses of antitoxin up to date by producing statistics for the five-month period September 1st, 1928, to January 31st, 1929, during which an epidemic, of as serious a character as that in Berlin, occurred in Copenhagen. The serum was provided by the State Serum Institute unconcentrated, and containing 0.1 per cent. chinosol. Serum for intramuscular injection contained 700 antitoxin units per cubic centimetre, and that for intravenous injection 800 to 1,600 units. For fear of protein shock the maximum dose for intravenous injection was fixed at 50 c.cm. for adults and 1 c.cm. per kilo body weight for children. If this amount of serum did not contain the required number of antitoxin units, the rest of the serum was given by intramuscular injection. For light cases up to 16,000 units were given, and when light cases were complicated by fetor, coryza, or severe periadenitis the dose was increased to a maximum of 60,000 units. In moderately severe cases the dosage usually ranged from 32,000 to 48,000, this dosage being doubled and, if necessary, repeated the next day when moderately severe cases were complicated by fetor, periadenitis, severe coryza, or a toxaemic appearance. In severe cases the dosage ranged from 80,000 to 100,000 on the patient's admission to hospital, and this dosage was increased by 50 to 100 per cent. if the case was complicated by severe coryza, fetor, periadenitis, etc. If the patient next morning still looked toxaemic, a second injection of 100,000 units was given. In the worst cases admitted a total of 300,000 to 500,000 units was given. In the five-month period under review 1,113 patients were admitted, and there were 23 deaths—a mortality of 2.07 per cent. By the exclusion of the 5 patients who died within twenty-four hours after admission—before which time serum treatment cannot fully exert its beneficial influence—the mortality was reduced to 1.62 per cent. Among the 687 light cases there were no deaths. Among the 315 moderately severe cases there were 3 deaths. Among the 111 severe cases there were 20 deaths. In the same period, but classed in a separate group, there were 46 cases of croup, 9 of which terminated fatally. The total mortality for faucial diphtheria and croup was 2.8 per cent. (1,159 cases, among which were 32 deaths).

519. Treatment of Typhoid Fever by the Bacteriophage.

A. BRETON (*C. R. Soc. de Biologie*, March 28th, 1930, p. 1016) records four cases of severe typhoid fever treated by intravenous injection of a bacteriophage which had been isolated from a typhoid convalescent patient some months previously; 1/400,000 c.cm. added to 10 c.cm. of broth inoculated with the corresponding typhoid bacillus produced complete lysis of this organism. The doses ranged from 0.4 to 2 c.cm. In three cases a rapid and complete recovery was obtained after one to three injections, but the fourth patient died four hours after a single injection of 0.4 c.cm. Each of the injections gave rise within twenty to seventy minutes (1) to more or less violent symptoms of shock lasting for twenty minutes, followed by refreshing sleep; (2) to a rise of temperature persisting for two hours, and followed by a considerable fall lasting on the average twenty-four hours. Convalescence then set in, either at once or a few days after the last injection. Breton considers that cure in his cases was due not to shock but to the specific action of the bacteriophage, since in healthy subjects or patients with a temperature of 104° intravenous injection of the same quantity of broth produces a much less violent shock than that caused by the bacteriophage, and does not bring about a similar fall of temperature. The bacteriophage employed was a very active stock strain.

520. Treatment of Sea-sickness.

ACCORDING to H. SEEL (*Med. Klinik*, April 4th, 1930, p. 514) sea-sickness is caused by disturbance of the semicircular canals and by psychic factors, both acting through stimulation of the vagus. Vagotonic individuals are the most likely to suffer. The therapeutic effects of atropine and hyoscyamine are, he considers, uncertain, possibly because, though they cause peripheral inhibition, they stimulate the vagus centre. Starkenstein experimented, therefore, with a combination of hyoscyamine and scopolamine, since the latter drug inhibits both centrally and peripherally; 1 mg. of these alkaloids administered orally beforehand prevented nausea in rotation experiments. Compounds of the drugs with camphoric acid are less toxic, and produce less dryness of the mouth, than the more generally used sulphates and chlorides. During a somewhat stormy Atlantic passage Seel confirmed the efficacy of this treatment, which, however, is more successful as a prophylactic than as a therapeutic measure. The combination of scopolamine and hyoscyamine is administered in tablet form. In a few very resistant cases, where sickness has already set in, subcutaneous administration is said to be necessary as a temporary measure.

Disease in Childhood.

521. Recovery from Pneumococcal Meningitis.

H. N. STOESSIGER (*Brit. Journ. Child. Dis.*, January–March, 1930, p. 35), who records an illustrative case, remarks that recovery from pneumococcal meningitis is exceedingly rare, the disease in the opinion of some authorities being invariably fatal. Records of individual cases of recovery need careful investigation, as the diagnosis of the nature of an infection causing a purulent cerebro-spinal fluid is sometimes a difficult matter even for the expert. Avirulent cocci may closely resemble the pneumococcus, and the meningococcus may sometimes be mistaken for the pneumococcus. In at least three cases on record the pneumococcus was isolated from the cerebro-spinal fluid and definitely grouped in Groups 1, 3, and 4 respectively. In at least six other instances organisms with the characters of the pneumococcus are reported as having been recovered from the cerebro-spinal fluid. In some of the other cases the cerebro-spinal lesions were indicative of a generalized septic meningitis, and apparently typical pneumococci were seen in the films, but no mention is made of their successful culture. The initial cause of the meningitis varied; some were primary infections, while others followed pneumonia, otitis media, or frontal sinus disease. Treatment in the successful cases consisted in repeated cisternal and lumbar punctures, anti-pneumococcal serum, or intrathecal optochin (ethylhydrocupreine hydrochloride). Stoessiger's patient was a girl, aged 5, in whom the meningitis was secondary to otitis media. Gram-positive diplococci resembling pneumococci were seen in the cerebro-spinal fluid, which was otherwise typical of acute meningitis, but no cultures of the organism were obtained. Rapid recovery took place after two intrathecal and one intravenous injections of 0.5 per cent. mercurochrome solution. Since, however, the organisms seen in films of the cerebro-spinal fluid removed immediately before the injections were given were reported to be degenerate, the beneficial action of the mercurochrome, though apparent, is unproven.

522. Etiology of Infantile Spasmophilia.

H. J. GERSTENBERGER, J. I. HARTMAN, G. R. RUSSELL, and T. S. WILDER (*Journ. Amer. Med. Assoc.*, February 22nd, 1930, p. 523) remark that it has been noted for a long time that practically every spasmophilic infant is rachitic, but that all rachitic infants are by no means spasmophilic; also that the treatment which cures rickets ultimately also cures spasmophilia. The attention of the authors was focused on what they believe to be the logical explanation of the mode of development of infantile spasmophilia by noting the variation in the effectiveness of different antirachitic agents in rachitic infants. It was found that much depended on the kind and degree of rickets—that is, whether spasmophilic symptoms were present or not. If the rachitic infant had spasmophilic symptoms, *x*-ray pictures revealed in practically all cases evidences of past or present healing. In order to evaluate the effectiveness of such previous therapy, and also to know whether patients whose radiograms on admission to hospital showed no dependable signs of healing had or had not been previously thus treated, the regular practice of subjecting rachitic patients with or without spasmophilic symptoms on admission to antirachitic therapy in any form was postponed. Typical clinical and blood serum pictures of spasmophilia were seen to develop in such infants. The development was noted of typical spasmophilia due to interrupted therapy in two rachitic infants who were exposed to sunlight, and due to inadequate therapy in one rachitic infant who received human milk possessing some antirachitic powers. This additional evidence substantiates the theory, previously advanced by the authors, that three factors are essential to the development of infantile spasmophilia: rickets; exposure of the rachitic infant to the influence of the antirachitic in one form or another in a sufficient degree to produce some healing; and interruption of the exposure or inadequacy of the exposure.

523. Tuberculous Infection in Infancy.

J. A. MYERS and L. M. KERNKAMP (*Amer. Review Tuberc.*, April, 1930, p. 423) studied the results of the cutaneous tuberculin test in 532 infants, aged 2 years or under, most of whom were examined as out-patients. The epidermal test was usually employed, it having been shown that the results of the epidermal and intracutaneous tests for the first two or three years of life are nearly parallel. At the first examination 296 gave negative reactions; the remaining 236 were positive, and were followed up as far as possible in order to ascertain the relationship between the history of exposure, physical signs, *x*-ray findings, and the present condition, with a view to prognosis. Of the 236 negative cases there was a history of exposure in 233, and of the 236 positive cases such a history was *definite in 195 and doubtful in 22. There is* reason to believe that some time elapses after bacilli enter the body before sensitiveness to tuberculin becomes manifest. The authors found the tuberculin test, *x*-ray examination, and a history of exposure to be of the greatest diagnostic value, and they believe that when the disease has developed the first step in treatment should be to prevent further exposure. Diet, hygiene, and heliotherapy are useful, but it must be borne in mind that many infants recover without any special treatment. The majority of those affected in infancy were found to be healthy at school age, many of them never having been ill; of 172 who were traced, only six had died of tuberculosis. The authors maintain that, in order to prevent infection and disease, the infants in tuberculous families should be separated from their mothers at birth, and effective pasteurization of milk be ensured.

524. Acute Endocarditis in Infants.

IN view of the comparative rarity of acute endocarditis in infancy, A. LOFFREDO (*La Pediatria*, March 15th, 1930, p. 311) reports two cases. A baby, aged 17 days, was admitted to hospital with gonorrhoeal ophthalmia; whooping-cough ensued, followed by death. During life no signs of cardiac disease were detected, but at the necropsy there was evidence of acute verrucous endocarditis. In the second case a premature weakly baby was admitted suffering from thrush; death was caused by broncho-pneumonia and progressive wasting. A systolic murmur was audible at the apex, and there was slight enlargement of the heart. At the necropsy subacute verrucous endocarditis and mitral stenosis were found. In neither of these patients was the cardiac condition congenital; in the second case the endocarditis was probably septic and secondary to the thrush.

Obstetrics and Gynaecology.

525. Regional Vaccine Therapy in Salpingitis.

A. BASSET and P. POINCLOUX (*Presse Méd.*, March 22nd, 1930, p. 401) discuss the regional application of vaccines in cases of non-tuberculous [illegible] bacterial suspensions being injected in [illegible] which have served as the port of entry [illegible] -organisms, however distant these groups may be from the site of the inflammatory processes. The results obtained in 43 cases of acute and subacute salpingitis have been encouraging, and better than could have been expected from other methods; in only two did operative intervention become necessary. Two essentials for successful treatment are the isolation of the causal organism and the correct selection of the tissue through which it invaded the body. To illustrate the principle of this therapy, three cases of salpingitis are recorded, one due to the gonococcus, one to *B. coli*, and one to a mixed gonococcal and coli-bacillary infection. In the first case, as in all gonorrheal conditions, the urethra was considered to be the port of entry of the pathogenic organisms, and the specific injections were therefore made into the urethral wall, Skene's glands being taken as a guiding point. In the second case the injections were made into the mucosa of the large intestine by means of an anal speculum and a syringe with a long needle such as is used for injecting haemorrhoids. In the third case injections of gonococcal and coli bacillary vaccines were made into their respective ports of entry, the former being first administered. The authors believe that a greater knowledge of pathogenic bacteria and of the sites where they enter the body, together with a perfecting of technique, will lead to still better results.

526. Haemoglobin Reduction in Pregnancy.

A. SCHRUMPF (*Norsk Mag. f. Laegevid.*, March, 1930, p. 311) reviews the literature, and describes the results of 1,500 haemoglobin examinations carried out in the obstetrical department of the Krohgstotten Hospital, Oslo. In more than 75 per cent. the haemoglobin concentration just before delivery was less than the normal as determined by examination of nurses and students, in whom the average concentration was found to be 0.142. During delivery it was reduced from 0.124 ante partum to 0.119 post partum, the reduction being considerably greater in cases with haemorrhage of more than 100 grams. More than 60 per cent. of the tests made before delivery, more than 65 per cent. of post-partum tests, and more than 80 per cent. of the post-partum analyses in cases with haemorrhage showed the haemoglobin-concentration reduced below the normal minimum of 0.130. The reduction of the haemoglobin concentration after delivery seemed to be greater for the ages 16 to 25 years than for the ages 26 to 35, while the reduction seemed to be more distinct for the ages 25 to 35 in cases of post-partum haemorrhage.

Finally, the average haemoglobin concentration ante-partum in cases without haemorrhage was higher than the ante-partum haemoglobin concentration in cases in which haemorrhage subsequently took place, though the difference was very small. Schrumpf is inclined to connect the reduction of haemoglobin during pregnancy and delivery partly to the increase of plasma, but mainly to the transmission of iron to the child. He therefore recommends that women whose haemoglobin concentration is much reduced should be treated with iron before and after delivery, and suggests that the oligosideraemia of breast-fed children during the first six months of life is sometimes the result of the mother's anaemia.

527. Pyelitis in the Puerperium.

G. C. PRATHER and E. G. CRABTREE (*New England Journ. of Med.*, February 20th, 1930, p. 366) consider that the occurrence of pyelitis during the puerperium is more frequent than is generally recognized; they maintain that it should always be considered as a possible cause of puerperal fever. Although not so frequent as the pyelitis of pregnancy, it occurred in about 0.4 per cent. of the deliveries at the Boston Lying-in Hospital during the years 1925–29; it was found that 48 per cent. of these cases were primiparae. Trauma during delivery, which was more frequent in primiparae, appeared to be the most frequent etiological factor. Very few cases gave a history of previous urinary tract infection, but post-partum bladder complications were present in at least 25 per cent. before pyelitis set in. A noteworthy point was that local symptoms might be absent although the pyelitis was responsible for the rise of temperature. The finding of pus in a catheter specimen associated with costo-vertebral tenderness was the most reliable clinical sign in making the differential diagnosis from pelvic sepsis. Cystoscopy had occasionally to be employed in order to establish a diagnosis. The author considers that there is relatively little danger of infecting a normal kidney, even though there is cystitis, if the bladder is washed thoroughly with a mild antiseptic before cystoscopy is performed, and some antiseptic is left in the kidney pelvis. Conservative treatment with the forced injection of fluids up to 150 ounces daily, and one of the urinary antiseptics given by mouth, produced the best results. The after-treatment of these cases is important; the author tries to keep in touch with them for four months. At the expiration of that period he expects them to have a sterile urine if there is no kidney lesion except the pyelitis. The importance of the urine becoming sterile before a succeeding pregnancy is also emphasized.

528. Pregnancy and Labour in Congenital Syphilis.

H. BOAS and T. SODERMANN (*Urol. and Cut. Rev.*, January, 1930, p. 23) record their observations on 39 women, subjects of undoubted congenital syphilis, with a total of 56 pregnancies. Unlike Fruhenholtz and Abramowitz, they did not find that these mothers were more liable to the complications of pregnancy and labour than normal women, apart from the fact that the nephritis of pregnancy appeared to be more frequent than usual. It was as a rule, however, only transient, mild in character, and not likely to recur. The 41 children born were found to be clinically, serologically, or at necropsy free from syphilis; there were two cases of abortion, and 13 children could not be traced.

Pathology.

529. The Physiopathology of Renal Disease.

M. GELERA (*Il Policlinico*, Soz. Med., February 1st, 1930, p. 63) reviews the extensive literature on the chemical changes of the blood in Bright's disease, and comments on twenty-two clinical cases. He classifies them as nephrosis or nephritis as follows. In nephrosis the calcium is diminished, the potassium increased, cholesterin greatly increased, glucose lowered within physiological limits, and the alkaline reserve is very high. In nephritis not accompanied by oedema the calcium is sometimes increased but is otherwise normal or diminished, the potassium is slightly increased, the cholesterin is increased but to a less extent than in nephrosis, the glucose is increased; the alkaline reserve was diminished except in three cases. In nephritis with oedema the calcium is diminished, the potassium increased, the cholesterin is moderately increased, the glucose is not within the normal limits, and the alkaline reserve is high. Thus nephritis showed hypercholesterinaemia, hyperglycaemia, and acidosis, while in nephrosis there was marked hypercholesterinaemia, a normal or lowered glucose figure, and alkalosis. Vascular nephritis with diffuse oedema is excepted because, while these cases present all the symptoms of nephritis, the chemical composition of the blood is similar to that in nephrosis. These results confirm the hypothesis of Pende that the chemical changes in the blood found in cases of nephritis are due to excitation of the sympathetic, and those in nephrosis to excitation of the vagus. The author adds that these results have a practical value in the treatment of renal disease. In nephrosis meat may be allowed because it diminishes the alkalosis, and the kidneys can well eliminate nitrogenous substances. Milk may be allowed in small quantities on account of its sodium chloride, but eggs are prohibited because of the cholesterin they contain. The chlorides of ammonium and calcium are valuable in producing acidosis and at the same time diuresis. Adrenaline and thyroid extract are indicated as stimulants of the sympathetic system. In nephritis meat and eggs must be prohibited, and the diet be mainly vegetarian, with potatoes; alkaline salts are useful. No special remedy can be recommended to reduce the stimulation of the sympathetic.

530. The Etiology of Psittacosis.

E. SACQUÉPÉE and L. FERRABOUC (*Presse Méd.*, April 26th, 1930, p. 569) record a series of experiments which were undertaken to elucidate the uncertain etiology of psittacosis. It was noted that the whole brood from which came a parrot that had apparently infected a certain patient were dead in a few weeks, and three of these birds were used as the test material. The livers, hearts, and lungs were examined, and studies were also made as to the mode of transmission of the infection. Since no micro-organisms, particularly streptococci and bacilli of the typhoid-paratyphoid group, could be isolated, attention was directed to the possible existence of a filterable virus. The experiments led to the conclusion that such a virus does exist; this confirms the findings of Bedson, Western and Levy Simpson, and Pesch. This virus could be transmitted from bird to bird, and was found in the organs and faeces. The authors believe that it is usually transmitted by the faeces, and also possibly by virulent droplets of sputum. The latter was considered as a possible source, since very marked unilateral pulmonary congestion was found in one parrot. The serum of convalescent cases of psittacosis seemed to be capable of slightly attenuating the pathogenic action of the virus, but to possess no curative power.

531. Effect of Vitamin Administration on Experimental Infections.

W. PFANNENSTIEL and B. SCHARLAU (*Münch. med. Woch.*, April 11th, 1930, p. 619) report experiments on pulmonary tuberculosis, and on staphylococcal skin infections in rabbits. As sources of vitamins they used cod-liver oil (A), dried yeast (B), and irradiated ergosterol (D). In pulmonary tuberculosis they found that none of these substances administered alone had a very certain effect, though in some of the animals receiving cod-liver oil the disease ran a less severe course. A combination of vitamins D and B, however, was effective, the infection being less severe, the tubercles more encapsulated, and metastases in other organs less common. In rabbits inoculated subcutaneously with haemolytic staphylococci, vitamins B or A alone had little effect, though recovery was quicker if both were administered. Animals treated with vitamin D showed only small sharply defined abscesses, which healed in fourteen days; the controls required about four weeks. With both yeast and ergosterol (B and D) the effect was especially good, healing occurring often within a week. The administration of calcium, especially in combination with vitamin D, also had a favourable influence. Administration of vitamins B and D was tried in a few cases of human furunculosis with encouraging results.

532. Encephalomyelitis in the Fox.

C. LEVADITI, P. LÉPINE, and J. BAZIN (*C. R. Soc. de Biologie*, January 24th, 1930, p. 136) have met with two cases of encephalomyelitis in foxes. The first animal had been imported from Canada in December, 1928, and began to show symptoms of illness in July, 1929. The second animal was born and bred in France, and became ill in August, 1929, when six months old. Both animals were silver foxes, and both died. Histologically the cortex of the first animal showed encephalitis and perivasculitis; the vessels were surrounded with lymphocytes and mononuclear cells; there was proliferation of the microglia, chromatolysis, and deformation of the cortical neurones; the medulla and cord were free from lesions. In the second animal there was a mononuclear meningitis, and foci of cortical encephalitis without any definite perivasculitis were seen. There were polymorphs in the vessels, perivascular haemorrhages, chromatolysis, and intense vacuolation of the neurones. Experimentally the authors were able to reproduce the disease in a wild fox by intracerebral inoculation with virus received from America. The incubation period lasted seventy-eight days and the illness twelve days, after which the animal died. A necropsy revealed the presence of encephalomyelitis. It would appear, therefore, that the American virus may be virulent for European foxes.

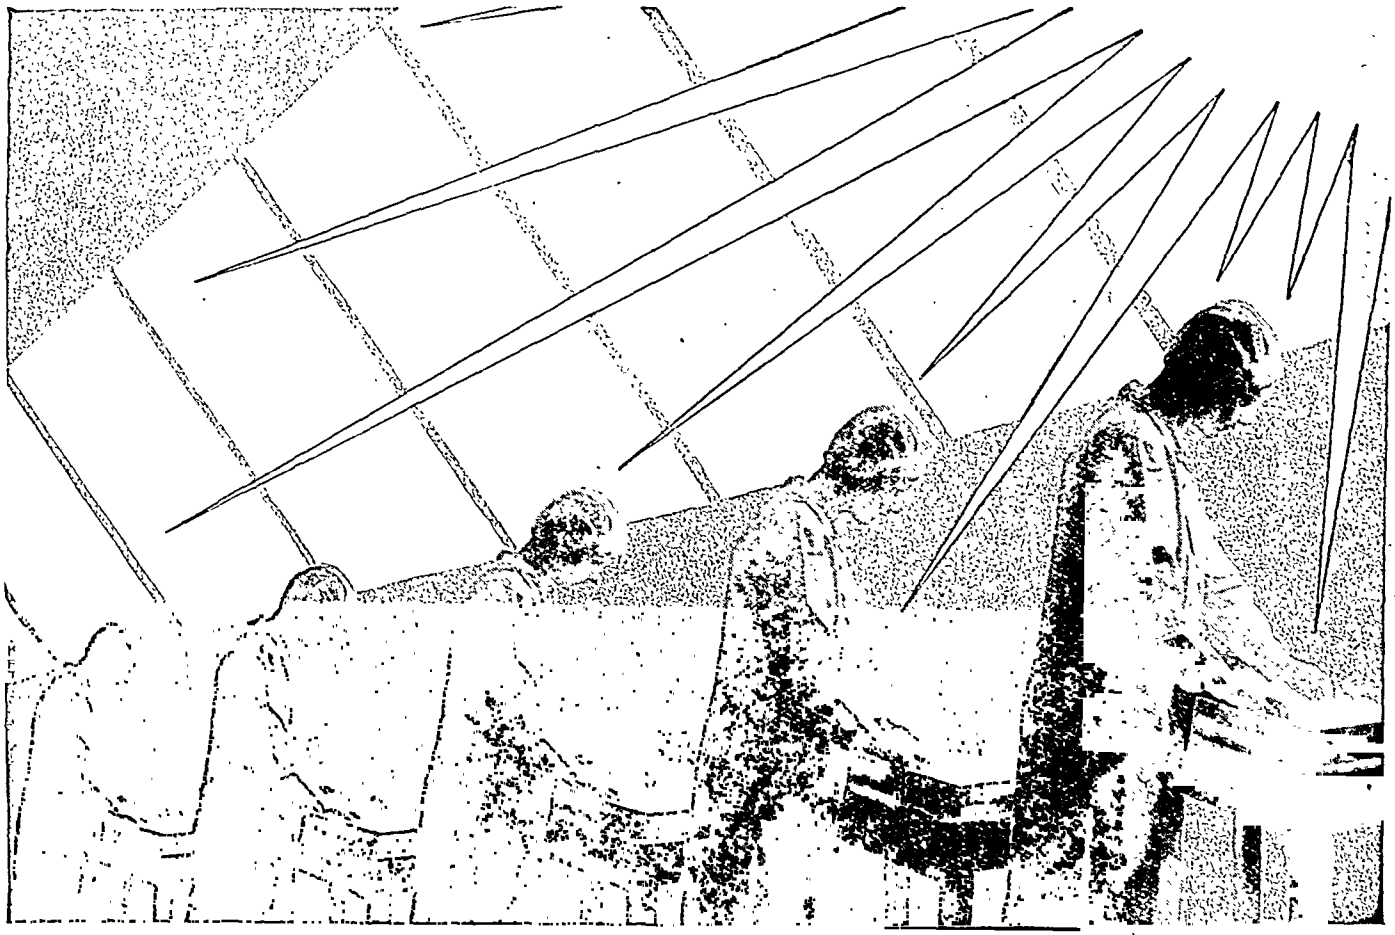
What about taste?

MANY patients still believe innocently that the medicine must be bitter to be efficacious.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is for that up to date generation that wants its medicines in the proverbial "sugar coating."

No excuses are needed for its taste any more than for its effectiveness. Agarol Brand Compound is exceptionally palatable without artificial flavouring. It *flows freely* from the bottle, and can be mixed with any liquid or soft food.

Just enough mineral oil to carry unabsorbable moisture to the intestinal contents, keep them soft, and so make evacuation easy and painless. By *gentle stimulation* of peristalsis, Agarol Brand Compound makes the result certain, and aids in re-establishing regular habits.



One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

FRANCIS NEWBERY & SONS, LTD., 31-33, Banner Street, London, E.C.1.

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists Since 1856.*

Because there are FEWER ULTRA-VIOLET RAYS IN TOWNS . . .

The health-giving ultra-violet rays penetrate smoky industrial areas even on dull, cloudy days. Recent research has proved this.

True they are cut down considerably by the smoke, but this, surely, is an added reason why they should be used instead of being wasted.

There are enough ultra-violet rays in towns to provide a gentle daily tonic of the utmost value to the health of the community. Through "Vita" Glass windows this tonic can be applied to hospital patients, school children, workers in offices and factories and people in their own houses. "Vita" Glass, which now costs scarcely more than twice the price of ordinary window-glass, is sold under guarantee to transmit the health-giving ultra-violet rays permanently. Write for full particulars to the "Vita" Glass Marketing Board, 9 Crown Glass Works, St. Helens, Lancashire.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers and Builders.

"VITA" GLASS

"Vita" is the registered Trade Mark of Pilkington Brothers Limited, St. Helens

BRITISH SPAS are best

and membership *of the* British Spas Federation is a guarantee of efficiency.

AT British Spas treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the Staffs are educated and properly trained, and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up-to-date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty, and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

A New Medical Handbook is being published, specially prepared for the use of the medical profession. A copy will gladly be sent you if you will write to the Hon. Secretary, Box 1, British Spas Federation, Thermal Baths, Buxton, or to the Managers of any of the Spas here mentioned.

BATH Hot Springs (120° F.). Radio-active. Royal Baths extensions now open.

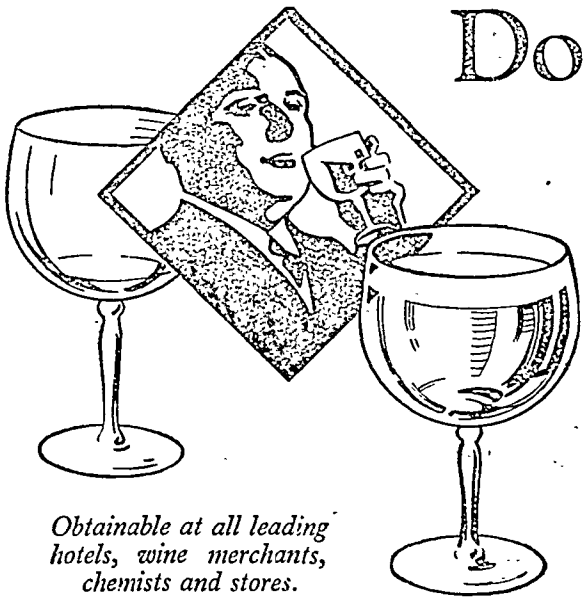
BUXTON Radio-active Mineral Water. New Natural Baths. 3 guineas Course.

CHELTENHAM Five Natural Waters. Modern Baths.

DROITWICH The Brine Baths Spa in charming Worcestershire.

HARROGATE 88 Waters. 100 treatments. Medically certificated staff.

LEAMINGTON Advanced Spa Treatment. Saline Springs.



LLANDRINDOD WELLS The Modern Welsh Spa.

STRATHPEFFER The Highland Spa. Strong Sulphur Waters.

TREFRIW WELLS Rich Sulphate Chalybeate Waters.

WOODHALL SPA Bromo-Iodine Waters. Pinewoods, restful air.

ANNOUNCEMENT *by the* BRITISH SPAS FEDERATION

Doctors have proved its worth

SIR HENRY THOMPSON, the eminent surgeon, in his treatise on "Food and Feeding" said:—

"For those who can afford to buy bottled waters, no purer exists in any natural source than that of our own MALVERN SPRINGS. Certainly, it is wholly unnecessary to import waters for the use of the table from foreign sources.

No foreign waters of any kind whatsoever are so pure or so cheap."

Obtainable at all leading hotels, wine merchants, chemists and stores.

Head Office:
1, Connaught Place, W.2.

MALVERN WATER

THE PUREST SPRING WATER

Write for the book of the Malvern Springs.

ANAESTHETICS

ANAESTHETIC ETHER

(DUNCAN)

S.G. 720

Duncan

Duncan's Anæsthetic Ether is absolutely pure and contains no aldehydes or other oxidation products.

It is the result of many years' experience in the manufacture of anæsthetics and can be used with confidence by the Anæsthetist.

Prices on Application.

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

A new building furnished with Baths and all modern Electrical Appliances for treatment was opened last Saturday, April 26th.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 1 grain of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures:—

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest.
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable. The Spa is under medical supervision and close co-operation is maintained with the patient's own physician.

Further particulars may be obtained at Belle Vue Spa or 7, Harley Street, W.1.

PREVENTION OF CANCER

ONE of the most noted authorities on Alimentary Toxæmia is firmly convinced of the importance of this condition in the production of Cancer.

The irritant effects of the stagnating contents of the bowel on the intestinal mucous membrane, accompanied as it often is with ulceration, is obviously a cause of Cancer in the bowel itself. According to this writer, the toxins absorbed produce atrophic changes in the breast and other organs which are specially prone to be followed by Cancer.

There are grounds, therefore, for hoping that the use of the most efficient of all intestinal disinfectants—Kerol—for prevention and cure of alimentary toxæmia, will do much to prevent the occurrence of Cancer.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Celestins,** by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

INGRAM & ROYLE, LIMITED,

Roboleine
THE FOOD THAT BUILDS THE BODY

ROBOLEINE contains all essential vitamins:—BONE MARROW: Yellow marrow from the long bones to stimulate formation of red corpuscles and so strengthen the whole nervous system. Red marrow from the rib bones to stimulate formation of white corpuscles and increase resistance to disease. MALT, a natural laxative and source of energy. EGG YOLK, containing lecithin, the greatest nerve food known. LEMON JUICE, neutralised for building bone and preventing skin trouble.

ROBOLEINE corrects Metabolism and is recommended in cases of Malnutrition, Debility, Sleeplessness, Loss of Weight, and in all Tuberculous conditions; also to Nursing and Expectant Mothers as a galactagogue, and as an adjunct in the Dieting of Infants, etc., etc.

ROBOLEINE is concentrated nourishment that revitalises the body and feeds the nerves. Easily assimilable, it is the best reconstructive tonic food available.

Samples sent gladly on request.

DIABETES

Brusson Bread has the lowest starch content of any starch-reduced gluten bread.

This low starch content enables a fuller and more varied diet to be enjoyed by the patient. Its scientifically graded content of protein and fat is definitely fixed, so enabling the physician to prescribe the correct quantity for each patient.

BRUSSON FOODS LTD 55 STATION Rd LONDON N.W.10

Free samples on request, with copy of "The Amplified Diet in Diabetes," often useful for handing to patients

every nurse should know . . .

A NURSE owes it to her own professional pride and to the safety of her patient to know the facts about Lysol.

When Lysol was first discovered a formula was worked out: a specification evolved for the manufacture of a perfect antiseptic and germicide. This is the formula: this the specification used to-day in the manufacture of Marshall's Lysol.

Marshall's Lysol costs a few pence more than other brands, because every bottle sold is uniform in purity: because every precaution that science teaches is taken to maintain this high standard.

Other Lysols may contain inferior ingredients: impurities may make them caustic, irritant . . . But Marshall's Lysol used as directed is harmless to skin and tissue: death to disease. It is an essential part of every nurse's equipment. Never use Marshall's Lysol undiluted.

Sample sent upon request to members of the Medical and Nursing Profession.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

FP834C

A Sedative Dusting Powder for ECZEMA.

Applied to eczematous parts, Emol-Keleet affords immediate and grateful relief from the distressing itching and burning. Emol-Keleet also possesses absorbent and mildly astringent properties which are effective in drying up the exudations in moist and purulent cases. Emol-Keleet is a natural product prepared from a pure, unctuous earth, entirely inorganic in composition, of a velvety-smooth texture, and exceptionally adhesive.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE-CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.
Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—
Dr. E. M. DOUGLAS MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

WONFORD HOUSE HOSPITAL,
EXETER, DEVON.

Telegrams: Exeter 2642. *Telephone*: Exeter 2642.

A registered Hospital for the treatment of patients of both sexes suffering from Nervous and Mental Disorders, situated in beautiful country within a mile and a half of the City of Exeter.

Hard and grass Tennis Courts, Croquet Lawn, Cricket Field, and all indoor amusements, Dancing, Concerts, Wireless, Billiards, Badminton. Occupational treatment.

The patients are carefully graded, and accommodation provides for the separate treatment of early recoverable and convalescent patients.

Voluntary and certified patients are received for treatment.

A prospectus and full particulars can be obtained from the Medical Superintendent.

BARNWOOD HOUSE,
GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L. M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.

For particulars as to terms, etc., apply to—
ARTHUR TOWNSEND, M.D., Resident Supt.
Telephone: No. 7 Barnwood.

CHEADLE ROYAL,
CHEADLE, CHESHIRE.

This registered Hospital for MENTAL DISEASES, with its seaside branch Glan-y-Don, Colwyn Bay, is for the treatment and care of PRIVATE PATIENTS of the UPPER and MIDDLE CLASSES. Voluntary Boarders received.

For terms, etc., apply to the Medical Superintendent, J. A. C. ROY, M.B., who may also be seen in Manchester by appointment.
Telephone: 481 GATLEY.

THE GRANGE,
near ROTHERHAM.

A HOUSE Licensed for the reception of a limited number of ladies suffering from Nervous and Mental disorders. Both certified and voluntary patients received. This is a large country house, with beautiful grounds and park, 5 miles from Sheffield. Station: Grange Lane, L. & N.E. Railway, Sheffield. Telephone: No. 40030 Ecclesfield. Resident Physician: GILBERT E. MOULD, L.R.C.P., M.R.C.S.

THE UNIVERSITY OF LIVERPOOL.

FACULTY OF MEDICINE.

THE MEDICAL SCHOOL provides complete courses of instruction for the Examinations of the University of Liverpool, and also meets the requirements of other Universities and Examining Bodies in the United Kingdom.

Other Schools of the Faculty are —The School of Dental Surgery, the School of Hygiene, the School of Tropical Medicine, and the School of Veterinary Science.

DEGREES AND DIPLOMAS IN THE FACULTY OF MEDICINE.

Bachelor of Medicine & Bachelor of Surgery	M.B., Ch.B	Master of Veterinary Science	M.V.Sc.
Doctor of Medicine	M.D.	Doctor of Veterinary Science	D.V.Sc.
Master of Surgery	Ch.M.	Doctorate in Philosophy	Ph.D.
Master of Hygiene	M.H.	Licence in Dental Surgery	L.D.S.
Master of Orthopædic Surgery	M.Ch.Orth.	Diploma in Public Health	D.P.H.
Bachelor of Dental Surgery	B.D.S.	Diploma in Tropical Medicine	D.T.M.
Master of Dental Surgery	M.D.S.	Diploma in Tropical Hygiene	D.T.H.
Bachelor of Veterinary Science	B.V.Sc.	Diploma in Veterinary Hygiene	D.V.H.
		Diploma in Medical Radiology & Electrology	D.M.R.E.

Valuable Fellowships, Scholarships, and Prizes are offered for competition each year.

THE CLINICAL SCHOOL consists of FOUR GENERAL HOSPITALS: The Royal Infirmary, the Royal Southern Hospital, the David Lewis Northern Hospital, and the Stanley Hospital; and of FIVE SPECIAL HOSPITALS: The Eye and Ear Infirmary, the Hospital for Women (including the Samaritan Hospital), the Royal Liverpool Children's Hospital, the Liverpool Maternity Hospital, and the St. Paul's Eye Hospital.

These Hospitals contain in all about 1,500 Beds.

The organization of these Hospitals to form one teaching Institution provides the Medical Student and Medical Practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom.

Infectious Diseases are studied in the Local and District Hospitals, and Mental Diseases at the County Mental Hospital, Rainhill.

For information on all matters concerning the curriculum application should be made to the Dean of the Faculty of Medicine, the University of Liverpool.

W. J. DILLING, Dean.

Applications, stating age, qualifications, and copies of testimonials, should be sent to the undersigned not later than June 11th.

MORRIS LODGE, Hon. Sec.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank	Service in Rank.	Basic Pay.	Overseas Pay	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office in July, and the selected candidates will be required to join a course of instruction commencing early in August, 1930. Applications should be submitted as soon as possible.

THE MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND, LIMITED.

Secretaries and Registered Office: Millar, Thomson & Dunlop, C.A., 113, St. Vincent Street, Glasgow.

ANNUAL SUBSCRIPTION £1. ENTRANCE FEE 10/-.

No entrance fee to those joining within 12 months of obtaining qualification. Benefits include defence of claims for alleged negligence in professional work, including indemnity of £2,500 and costs; and advice on professional difficulties.

Particulars and forms of application can be obtained from the Secretaries at the above address.

County Borough of West Ham.

PUBLIC ASSISTANCE COMMITTEE.

CONSULTING OPHTHALMIC SURGEON.

Applications are invited for the appointment of Consulting Ophthalmic Surgeon for one afternoon fortnightly, at a salary of £100 per annum, at the WHIPPS CROSS HOSPITAL, Whipps Cross Road, Leytonstone, E.11.

Applicants must be definitely of consultant rank and must be attached in that capacity to some Special Hospital or to a corresponding Special Department of a General Hospital.

The duties will consist of making visits to the Hospital, there to treat (or advise as to treatment in) such cases as are selected by the Medical Superintendent. The duration of each visit will vary with the number of cases arising. Emergency visits, if any, will be very rare.

The services of the Consultant will be retained for a period of one year in the first instance, and he will be required to provide his own Locum Tenens during holidays and absences.

Applications, with copies of not more than three testimonials, should be made to the undersigned not later than Saturday, June 14th.

CHARLES E. CRANFIELD,
Public Assistance Offices, Town Clerk.
Union Road, Leytonstone, E.11.
May 27th, 1930.

County Borough of Middlesbrough.

RESIDENT MEDICAL OFFICER.

Applications are invited for a Male Assistant Resident Medical Officer for the Fever Hospital, who will also be required to assist the Medical Officer of the Port of Middlesbrough and undertake such other duties as may be required under the direction of the Medical Officer of Health. Preference will be given to candidates with a Diploma in Public Health and a knowledge of the work of a Port Sanitary Authority.

Salary £450 per annum, with board, residence, laundry, etc.

Applications, stating age, qualifications, experience, and when able to take up duties, accompanied by copies of three recent testimonials, to be sent to the undersigned not later than Saturday, June 14th.

Municipal Buildings, PRESTON KITCHEN,
Middlesbrough Town Clerk.
May 27th, 1930.

Swansea County Borough.

LADY ASSISTANT MEDICAL OFFICER.

The Swansea Borough Council invite applications from duly qualified and experienced women Medical Practitioners for the post of Assistant Medical Officer to assist with the Medical Services of the Corporation. Special experience in diseases of women (ante-natal and obstetrics) and children, school medical service, and mental deficiency work are desirable qualifications. Salary £600 per annum. Form of application and list of duties can be obtained from Dr THOMAS EVANS, Medical Officer of Health, Public Health Office, Swansea. Applications must be received not later than Thursday, June 26th.

County Borough of Swansea.

ASSISTANT SCHOOL DENTAL SURGEON.

Applications are invited from registered Dental Surgeons for the above appointment. Salary £450 per annum, rising by annual increments of £25 to £550. Applications (on special form to be obtained from the Medical Officer of Health, Public Health Office, Swansea) to be received not later than Thursday, June 26th.

East Suffolk and Ipswich Hospital.

(265 Beds—7 Residents.)

Wanted end of June, HOUSE PHYSICIAN (male, British). Salary at the rate of £120 per annum, with board, residence, and laundry. Applications, stating age, qualifications, and experience, and accompanied by three recent testimonials, to be sent to the undersigned.

The Hospital, ARTHUR GRIFFITHS,
Ipswich. Secretary.

City and County of Kingston-upon-Hull.

APPOINTMENT OF TUBERCULOSIS OFFICER.

The Corporation invite applications for the post of Clinical Tuberculosis Officer at a commencing salary of £800, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £1,000 per annum. The age of candidates is not to exceed 40 years.

Candidates should either have held a previous appointment as Tuberculosis Officer with the approval of the Ministry of Health, or should, subsequent to qualification—

(1) Have had at least three years' experience in the practice of their profession;
(2) Have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general Medical or Surgical cases; and
(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis.

The gentleman appointed will rank as a Senior Assistant Medical Officer of Health, and will work under the general administrative control of the Medical Officer of Health.

As the post is a designated post under the Local Government and Other Officers Superannuation Act, 1922, the successful candidate will be required to undergo a medical examination.

Forms of application, which are obtainable from the undersigned, should be returned so as to be received not later than June 14th.

N.B.—This advertisement is again being issued owing to the withdrawal of the candidate appointed in April on account of his accepting subsequently another post.

Health Dept., W. M. FRAZER,
Guildhall, Medical Officer of Health.
Hull. May, 1930.

Panel Committee for the County of London.

ORGANISING AND ASSISTANT MEDICAL SECRETARY.

The Committee invites applications from registered Medical Practitioners for the appointment of Organising and Assistant Medical Secretary. The duties will consist of visiting and advising practitioners on the panel in the area, organising local medical associations, and assisting the Medical Secretary, giving his whole time to the duties.

Salary £600 per annum, with an allowance of £104 per annum for expenses. The appointment will be in the first instance for one year, subject to six months' notice on either side.

Applications, stating age and experience, should be sent to the Medical Secretary, London Panel Committee, 17, Russell Square, W.C.1, not later than June 16th.

C. L. BATTESON,
Medical Secretary.

Beckett Hospital & Dispensary, BARNSLEY.

The Committee invite applications for the post of HOUSE PHYSICIAN. Applicants must be registered and hold a Medical and Surgical qualification, and preference will be given to applicants who have held a previous Hospital post and having Pathological experience.

Salary £200 per annum, with board, residence, and laundry.

Applications, together with testimonials, should be sent to the undersigned not later than Thursday, June 19th.

ARTHUR L. BOURNE,
May 29th, 1930. Secretary-Supt.

Kent County Council.

Wanted, LOCUM TENENS, with Sanatorium or Hospital experience, for seven weeks commencing July 11th, to act as ASSISTANT MEDICAL OFFICER at the COUNTY SANATORIUM, LENHAM (165 beds).

Salary 8 guineas per week, in addition to board, lodging, and washing.

Apply, stating age and experience—

ALFRED GREENWOOD, M.D.,
Sessions House, County Medical Officer.
Maidstone. May 30th, 1930.

Lancashire County Council.

PUBLIC ASSISTANCE COMMITTEE.

PARK HOSPITAL, DAVYHULME, near MANCHESTER.

APPOINTMENT OF RESIDENT MEDICAL OFFICERS.

Applications are invited from registered Medical Practitioners (men) for the appointment of—

(a) SENIOR RESIDENT MEDICAL OFFICER, at a salary at the rate of £250 per annum.
(b) SECOND RESIDENT MEDICAL OFFICER, at a salary at the rate of £225 per annum.

Candidates should be unmarried.

The appointments will, in the first instance, be for a period of six months. The successful applicants, however, will be eligible for re-appointment for a further period of six months at the end of that period.

In addition to the salary the Resident Medical Officers will be provided with the usual residential allowances.

The Hospital comprises 500 beds.

Applications, accompanied by copies of not more than three testimonials, should be addressed to the County Medical Officer, Public Assistance (Hospital and Medical) Department, County Offices, Preston, not later than June 21st. Envelopes should be endorsed "Senior Resident Medical Officer" or "Second Resident Medical Officer."

County Offices, GEORGE ETHERTON,
Preston. Clerk of the County Council.
May 28th, 1930.

City and County of Bristol.

CHIEF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT PORT MEDICAL OFFICER.

The Corporation of Bristol invite applications for the post of Chief Assistant Medical Officer of Health and Assistant Port Medical Officer.

The gentleman appointed must possess the Diploma in Public Health or a similar qualification in State Medicine. He will be required to devote the whole of his time to his duties and will not be allowed to engage in private practice. He will work under the direction of the Medical Officer of Health in the City Health Department and in the Port, and also in the Inspection of Aliens if appointed to do so by the Ministry of Health. The appointment will be subject to one month's notice on either side and to the provisions of the Local Government and Other Officers Superannuation Act, 1922, for which purpose the candidate will be required to pass a medical examination.

Salary will be £800, rising to £1,000 per annum by annual increments of £100.

Applications must be made on a prescribed form, which may be obtained from the undersigned, and must be delivered at the Council House, Bristol, not later than Friday, June 13th. Envelopes should be endorsed "Assistant M.O.H."

Canvassing of Members of the Council, either directly or indirectly, will disqualify.

The Council House, JOSIAH GREEN,
Bristol. Town Clerk.
May 26th, 1930.

North Riding Infirmary, MIDDLESBROUGH.

(General Hospital—150 Beds.)

SENIOR HOUSE SURGEON (male) required to take up duties middle of July, also JUNIOR HOUSE SURGEON to take up duties as early as possible.

Salary of Senior House Surgeon at the rate of £200 per annum and Junior House Surgeon £150 per annum, with board, residence, and laundry. Three residents are employed.

Appointments for not less than six months.

Candidates eligible for higher posts as they become vacant.

Applications, stating age, nationality, and previous experience, with three recent testimonials, should be sent to the undersigned as soon as possible.

CHARLES POSTGATE,
Secretary-Superintendent.

EAST AFRICAN MEDICAL SERVICE.

VACANCIES at present exist for MEDICAL OFFICERS in the EAST AFRICAN MEDICAL SERVICE.

Qualifications.—Candidates must be British subjects of European parentage and under 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

Salary.—£600 per annum, rising by annual increments of £30 to £840 per annum, and thence, subject to an efficiency bar, by £40 to £920 per annum.

Quarters.—Free quarters are provided or an allowance is given in lieu.

Passages.—Free first-class passages are provided both on first appointment and when proceeding on or returning from leave. A married officer will be granted an allowance towards the cost of his family's passage once each way in respect of each tour of service.

Terms of Appointment.—The appointments are pensionable subject to a probationary period of two years in the first instance.

Length of Tour of Service.—The normal tour of service is 20 to 30 months, after which leave is granted, with full salary, for 2½ to 3½ days, according to the districts in which the officer has served, for each month of service, plus the period of the voyage to England. If the officer is returning to East Africa for further service, he receives a further similar amount of leave, plus the period of the voyage to East Africa.

Course of Instruction in Tropical Medicine.—Selected candidates will normally be required to undergo a course of instruction in Tropical Medicine and Hygiene before proceeding overseas.

Duties.—Though Medical Officers are appointed in the first instance for general service, there are good opportunities for work in special branches of medicine and surgery and for research.

Further particulars and forms of application may be obtained on application, in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Onderstepoort, South Africa.

THREE RESEARCH FELLOWSHIPS.

Applications are invited for Three Research Fellowships tenable at the ONDERSTEPOORT VETERINARY RESEARCH LABORATORY, PRETORIA. These Fellowships have been established by the Empire Marketing Board in conjunction with the Government of the Union of South Africa.

Candidates will be required in each case to furnish proof that they are familiar with particular aspects of research, namely:

(1) *First Fellowship*, methods of tissue culture and work with filterable viruses;
(2) *Second Fellowship*, bacteriological work and the physiology of animals, especially ruminants;
(3) *Third Fellowship*, methods of extracting toxic substances from plants and determining the nature of such substances.

Selection will be made by a Committee consisting of the President of the Royal Society, the High Commissioner for the Union of South Africa in London, the Chairman of the Research Grants Committee of the Empire Marketing Board, and the Director of the Imperial Bureau of Animal Health.

The Fellowships will be tenable for a period of three years with the possibility of renewal for a further period of two years. Remuneration will normally be at a rate not less than £800 and not more than £1,000 per annum, but special consideration may be given to candidates whose qualifications and other circumstances warrant a higher rate.

Each successful candidate will be provided with a free passage for himself and his family from his place of residence to Pretoria. Duties should commence as early as possible.

During the tenure of the Fellowship the holder will be responsible to the Director of the Onderstepoort Laboratory.

Applications should be addressed to the Secretary, Empire Marketing Board, 2, Queen Anne's Gate Buildings, London, S.W.1 (cables "Empmart, London"), and should be received not later than September 1st, 1930.

Applications should be accompanied by six typed copies each of three testimonials and references to any published work.

CHARLES E. V. UPTON, Secretary.

Rhondda Urban District Council.

ASSISTANT MEDICAL OFFICER.

The above Council invite applications from male registered Medical Practitioners to act as Whole-time Assistant Medical Officer of Health and Assistant School Medical Officer, under the direction, supervision, and control of the Council's Medical Officer of Health, at a salary of £500, rising by annual increments of £25 to £700 a year, together with travelling expenses necessarily incurred in the performance of the duties.

Candidates must have had not less than three years' professional experience subsequent to registration, and the possession of a Diploma in Public Health is desirable.

The duties will pertain to both Public Health and School Medical Services, but experience in the work of school clinics, including the examination and certification of defective children, orthopaedic work, X-ray and ultra-violet radiation, and general anaesthesia for dental and throat operations will be considered to be of special importance.

The appointment will be subject to two calendar months' notice on either side and to the approval of the Board of Education. The officer appointed will be required to reside within the Rhondda Urban District and will not be allowed to engage in private practice.

The selected candidate may be required to pass a medical examination, and should the position become a designated post under the Local Government and Other Officers Superannuation Act, 1922, during the tenure of the successful applicant the necessary deductions will be made from the salary.

Applications are to be made on forms obtainable from the Medical Officer of Health, Tydfil House, Llewelyn Street, Pentre, Rhondda, by whom they must be received, endorsed "Assistant Medical Officer," and accompanied by copies of three recent testimonials, not later than Tuesday, June 17th.

The Council Offices, Pentre, Rhondda. June 3rd, 1930.
D. J. JONES, Clerk of the Council.

Administrative County of LONDON.

The LONDON COUNTY COUNCIL invites applications from qualified Medical Practitioners for appointment to the position of SECOND ASSISTANT MEDICAL OFFICER in its Public Health Department, for duty, in the first instance, at the SOUTHERN HOSPITAL, DARTFORD, KENT. Candidates must have had at least twelve months' residential experience in a Fever Hospital. The provisional commencing salary is £550 a year, a deduction of £130 a year being made for board, lodging, and laundry. The salary, deductions for board, etc., and the conditions of service are subject to review by the Council. The candidate appointed will be required to reside on the premises, and there is no suitable accommodation for a married man or for women.

Application forms, containing full details, obtainable (stamped addressed foolscap envelope necessary) from the Medical Officer of Health (Staff Division), The County Hall, Westminster Bridge, S.E.1. Forms must be returned by Friday, June 13th. Canvassing disqualifies.

The County Hall, S.E.1.
MONTAGU H. COX, Clerk of the London County Council.

The King Edward VII Welsh NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered Practitioners for the appointment of LADY ASSISTANT RESIDENT MEDICAL OFFICER at the CEFN MABLY HOSPITAL, MICHAELSTONE-Y-VEDW, near NEWPORT (110 beds for male and female pulmonary cases).

Salary £250 per annum, plus maintenance, the appointment being limited to one year.

Applications, stating age, full qualifications, and experience, together with copies of three recent testimonials, should reach the undersigned not later than June 19th.

Memorial Offices, Westgate Street, Cardiff.
D. A. POWELL, Principal Medical Officer.

Bolingbroke Hospital (120 Beds), Wandsworth Common, S.W.11

Applications are invited for the post of RESIDENT MEDICAL OFFICER (male).

The appointment is for twelve months from July 1st next.

Salary £200 per annum, with board, residence, and laundry.

Candidates must be fully qualified and registered.

Applications, stating age, qualifications, and experience, with copies of not more than three testimonials, should be sent to the undersigned on or before June 12th.

W. S. RANDOLPH BISS, Secretary-Superintendent.

Rhondda Urban District Council.

ASSISTANT DENTAL SURGEON.

The above Council invite applications from persons of either sex, registrable as Dental Surgeons, to fill a vacancy for one Whole-time Assistant Dentist required for the examination and dental treatment of children attending the schools controlled by the Rhondda Education Authority, for giving instruction in hygiene of the teeth, for the dental treatment required in connection with the Council's Welfare Scheme, and for the performance of incidental duties.

The appointment will be subject to the approval of the Board of Education, and the officer appointed will be subject to two calendar months' notice on either side, and will be required to reside within the district, to abstain from private practice, and to act under the direction and control of the Council's Medical Officer.

The selected candidate may be required to pass a medical examination, and should the position become a designated post under the Local Government and Other Officers Superannuation Act, 1922, during the tenure of the successful applicant the necessary deductions will be made from the salary.

The salary offered is £450, rising by annual increments of £25 to £500 a year, expenses by rail or tram necessarily incurred in the performance of the duties being allowed.

Applications are to be made on forms obtainable from the Medical Officer of Health, Tydfil House, Llewelyn Street, Pentre, Rhondda, by whom they must be received, endorsed "Assistant Dental Surgeon," and accompanied by copies of three recent testimonials, not later than Tuesday, June 17th.

The Council Offices, Pentre, Rhondda. June 3rd, 1930.
D. J. JONES, Clerk of the Council.

Rotherham County Borough.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Public Assistance Committee invite applications for the above post at the Hospital, Alma Road, Rotherham.

Salary £150 per annum, together with the usual residential allowances.

Candidates must be single, not exceeding 30 years of age, fully qualified and registered.

Applications, stating age, qualifications, etc., together with copies of three testimonials, to be sent to the Public Assistance Officer, 26, Moorgate Street, Rotherham, not later than June 16th.

SCHACHT'S

Original Preparations

FOR THE USE OF

THE MEDICAL PROFESSION.

LIQ. BISMUTHI "SCHACHT."

Absolutely pure and perfectly stable. The original preparation and the most physiologically active solution of Bismuth. Dose: One drachm, diluted.

PEPSINA LIQUIDA "SCHACHT."

A palatable, standardized solution of gastric juice from the pig. Useful in the treatment of dyspepsia. In ten-minim doses it gives excellent results in infantile diarrhœa. Adult dose: One drachm, diluted.

PEPSINA LIQUIDA C. BISMUTHO "SCHACHT."

Each fluid drachm contains in a concentrated form, besides the Pepsina Liquida, one fluid drachm of Liquor Bismuthi "Schacht." Dose: One drachm, diluted.

PEPSINA LIQUIDA C. BISMUTHO CO. "SCHACHT."

Contains one grain of Soluble Euonymin in each fluid drachm, in addition to the Pepsine and Bismuth. Dose: One drachm, diluted.

BISEDIA.

A combination of Schacht's Liquor Bismuthi and Pepsina Liquida, with Morphia and Hydrocyanic Acid. Of the greatest value in the treatment of Acute Dyspepsia, Gastric Ulceration, Vomiting of Pregnancy, etc. Dose: Half to one drachm, diluted.

LIQ. CASCARÆ DULCIS "SCHACHT."

A palatable and very concentrated aromatic preparation of the finest Cascara Sagrada; free from bitterness and griping action. Dose: Quarter to one drachm.

LENIVA.

An excellent fruit laxative syrup, containing Alexandrian Senna, Figs, Prunes, Tamarinds, etc. Eminently suitable for delicate women and children. Dose: Half to two drachms, according to age.

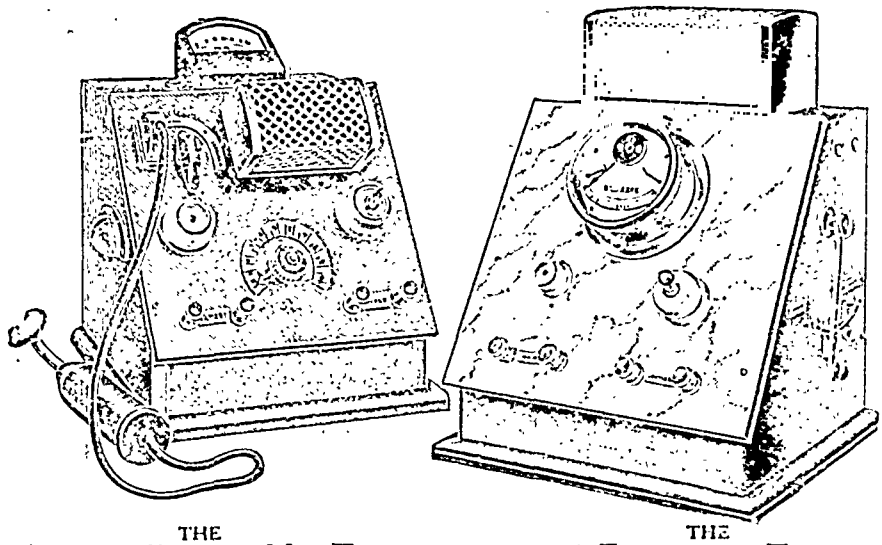
NIGHT OR MORNING?—WHEN TO TAKE LAXATIVES

There can, of course, be no universal rule as to the taking of laxatives. Circumstances vary, and only the physician is in a position to judge their relevance. But experience seems to show that a good deal of harm is often done by the common habit, continued over long periods, of taking aperients at bed-time. At night, the colon is normally much less active than in the day; and it seems unwise, unless special reasons exist, to stir it to unwonted activity during the hours which should be allotted to sleep. It is probable that much insomnia and many rest-disturbing dreams have their origin in the taking of a nightly purgative.

When there is an habitual tendency even to slight constipation, not fully remedied by diet and exercise, it is suggested that the most satisfactory result can generally be obtained by the taking, first thing in the morning, on an empty stomach, of a simple refreshing saline draught, such as Eno's "Fruit Salt" provides. Eno is a saline effervescent of fine granular consistency, containing no trace of irritating mineral salts, such as Epsom and Glauber. Owing to its purity and texture, it is agreeable to the palate; its pleasantness owing nothing to added sugar or flavouring matter, from both of which it is entirely free.

"*The Doctor's Emergency Reminder.*"

The Proprietors of ENO's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "The Doctor's Emergency *Reminder" summarises briefly a few points in connection with the treatment of* poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.



J. C. Eno Ltd., 160, Piccadilly, London, W.1.

ENO'S "FRUIT SALT"

DIATHERMY APPARATUS

FOR THE GENERAL PRACTITIONER

Thermo-penetration or Diathermy Treatment is receiving extraordinary attention on the part of the medical profession owing to its manifold uses and the unquestionably satisfactory results obtained in treatment.

SURGICAL SERVICE
SALTAIR

"SALTAIR SURGICAL SERVICE"

SALT'S Patent GASTROPTOSIS BELT

Front View.

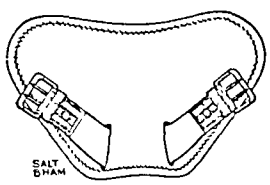

Fig. A.
Front View of Springs and Pad.

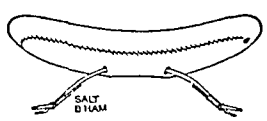

Fig. B.
View from top showing thickness of spongy rubber pad and position of steel springs.

This belt was designed by us in co-operation with a well-known X-ray specialist.

It is so constructed that its upper part allows of free expansion of the abdomen, whilst the lower part and pad are fixed. The support consists of a metal plate padded with spongy rubber and having transverse springs. On pressure being applied by the springs, the pad sinks into the soft abdominal tissues, so that, on the patient rising, it is impossible for the stomach to drop below the upper margin of pad.

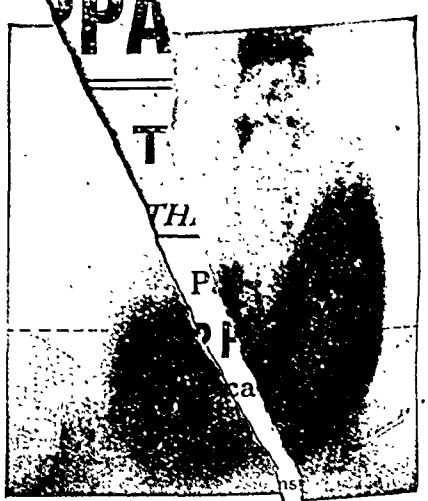

Fig. A.
A slightly dilated and much dropped stomach radiographed immediately after partaking of a Barium (6 ozs.) "Umbrose" Meal. The greater curvature projects 3½ in. below a line drawn from one iliac crest to the other.
(Taken in the upright position.)

Fig. A.

Actual reproductions of X-ray photographs (Figs. A & B) prove the efficiency of the support.

STANIFORM
Regd. BRAND Trade Mark.
METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I continue to get every satisfaction from 'Staniform' in the case of carbuncles, boils, whitlows, and all kinds of infected wounds."
"In a case of acute eczema on leg, the skin was quite normal within one week after starting application of 'Staniform Ointment.'"
"Festering wound on left heel when first seen was about the size of a shilling with good deal of pus. Foot much swollen—dressed with 'Staniform Ointment' healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

A MEDIUM FOR THE PEAT DISTILLATE PRINCIPLE

THE peat distillate principle, an acknowledged remedy for skin troubles, has been put into harness, in the shape of sphagnum moss, by the surgeon. It has found its way in the shape of bog water, into the age old pharmacopoeia of the Irish peasant. In both instances it has justified its use again and again.

The makers of Sphagnol preparations have devised a variety of convenient media for this principle, an ointment, soaps (Medical, Toilet, and Shaving), a lotion and suppositories. In each case the strength is from 5 to 15 per cent. and the medium of the highest quality. The preparations are on sale at all chemists at very reasonable prices.

Medical practitioners who would like to test the maker's claim will be supplied with generous free samples on application to Peat Products (Sphagnol) Ltd. (Dept. B27), 21, Bush Lane, London, E.C.4.

DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only the finest China should be drunk. Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of the finest China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

Priced at 3/- and 3/8 per lb. A super quality at 4/2 per lb.

HARDEN BROS. & LINDSAY, LTD.
(Dept. 153), 30/34, Mincing Lane, London, E.C.3.

CYS.6

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

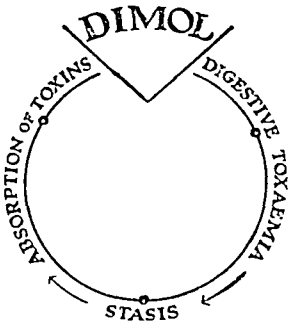
For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.



In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Break the Vicious Circle in Chronic Constipation

THOUGH THE differential action of many of the toxins of the intestinal tract on the tissues of the body is still a matter of conjecture, it is probable that each putrefactive organism creates a toxin productive of some deleterious effect. It is on this hypothesis that constipation is primarily ascribed to the influence of some of these poisons acting directly on the musculature of the bowel or on the nerve cells and ganglia in its walls.

HOWEVER THE diminished peristaltic action is caused, it is certain that it is the beginning of a vicious circle, which is completed by a deepening line of inertia, stasis, digestive toxaemia, and lowered resistance of the glands and cells of the mucosa.

TO BREAK THE vicious circle, an efficient, non-toxic intestinal disinfectant is clearly indicated; the resultant action is easy to understand. Now that the problem of intestinal disinfection has been solved by the introduction of the benzene derivative Dimol, we know that the putrefactive organisms can be destroyed, thus shutting off the further supply of toxin. The nerve cells, released from the paralysing action of the toxins, are once more free to stimulate the muscles, with the consequent result that peristalsis is re-established—the accumulated contents of the intestine are expelled and the vicious circle is broken.

Samples and Literature will be sent on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

Cremo-Carbonates

(Tri-Carb-Cream-Mulford)

Effective
Non-Caustic
Palatable

H. K. MULFORD
COMPANY LTD.
Regent Arcade House,
252, Regent Street,
London, W.1

CREMO-CARBONATES presents certain unique features which warrant its preference whenever an antacid and corrective is indicated. For the first time the well-known protectives and antacids—bismuth, magnesia, and lime—are supplied as a suspension of particles of colloidal dimensions.

Its colloidal nature gives it maximum covering power superior to that of a mere mechanical mixture of bismuth, magnesium, and calcium.

CREMO-CARBONATES is a soothing antacid, corrective, and digestant, particularly useful in the treatment of hyperacidity accompanied by flatulence and of any other conditions where there is excessive secretion of the gastric juices.

Literature and samples sent free to members of the medical profession.

OVALTINE

IN GALACTOSIS

Diet in lactation is a matter of no less importance than diet during pregnancy.

"Ovaltine" completely meets the requirements of the diet of the nursing mother by providing adequate and appropriate nourishment.

It is easily digested, wholly nourishing, and does not convey any noxious or unpalatable substances to the breast milk. For these reasons "Ovaltine" will be found a most dependable prescription for establishing galactosis.

"Ovaltine" is recommended to be given about the sixth month of gestation and should be continued throughout the nursing period. A rich milk secretion is thus encouraged and the health of the patient safeguarded against overstrain.

As an example of the nutritive power of "Ovaltine" it may be stated that one cupful yields more nourishment than 3 eggs or twelve cups of beef-tea.

A liberal supply for clinical trial sent free on request.

EPHEDRINE B.D.H.

In Hay-Fever Treatment

The value of Ephedrine B.D.H. in hay-fever lies in its power to reduce the sensitiveness of the mucous membrane and to contract the capillaries; hence the quick relief that it affords from the nasal congestion associated with this condition.

Ephedrine B.D.H. is issued specially for Hay-Fever treatment as follows:—

Ephedrine B.D.H.
Inhalant
A solution of Ephedrine B.D.H. in liquid paraffin

Ephedrine B.D.H.
Inhalant Compound
Containing camphor, menthol and oil of thyme in liquid paraffin

Ephedrine B.D.H.
Nasal Spray
An aqueous solution of Ephedrine Hydrochloride B.D.H.

Ephedrine B.D.H.
Nasal Jelly
Containing Ephedrine B.D.H. in pure petroleum jelly

MONSOL *in* MIDWIFERY

An authority on the subject has expressed the considered opinion that the use of Monsol in midwifery would reduce the incidence of Puerperal Sepsis by fully 90 per cent.

Bacteriologists and Clinicians have proved repeatedly that Monsol has a selective action on Streptococci—an action ten times greater than lysol (which cannot destroy these germs except at a concentration liable to injure the tissues).

Outstanding features of Monsol are:

1. A high germicidal power against the organisms that cause sepsis.
2. A bland and emollient action—non-irritating to the tissues and mucous membranes at therapeutic concentrations.
3. Low toxicity. (One-sixth as poisonous as lysol.)
4. Great power of penetration, reaching deep-seated inflammation.

Many Hospitals, Nursing Homes and Lying-in Institutions are now specifying the use of Monsol in all maternity cases. In addition to reducing the risk of infection, Monsol leaves the hands and skin soft and supple, a fact much appreciated by the Nursing Profession.

Monsol is the product of a Mond Laboratory, prepared under strict scientific control.

MONSOL
THE SAFE GERMICIDE

"BYNO" HÆMOGLOBIN

A Powerful Hæmatinic and Tonic

Presents the hæmoglobin, proteins and salts of fresh blood in combination with "Bynin," Liquid Malt. The hæmoglobin is prepared by a special process which conserves its physical properties and prevents decomposition, an important point since decomposition is accompanied by loss of therapeutic properties.

Advantages of "Byno" Hæmoglobin over inorganic iron preparations are its rapid absorption, greater hæmatopoietic effect, and its freedom from gastro-intestinal disturbances.

Indicated as a routine treatment in simple anæmias, in general debility and in convalescence.

Clinical trial samples and literature will be gladly sent on request.

Allen & Hanburys Ltd.

For quick relief in

Urinary Tract Infections

CAPROKOL

The first result of Caprokol administration is prompt relief from pain, burning, frequency and other unpleasant symptoms associated with pyelitis, cystitis, urethritis and similar infections of the urinary tract.

The beneficial effects, however, do not end here, for in Caprokol there are combined with the properties of a soothing anodyne those of a powerful germicide. Persistent treatment, therefore, not only brings symptomatic relief, but eventually effects the complete sterilisation of the urinary tract.

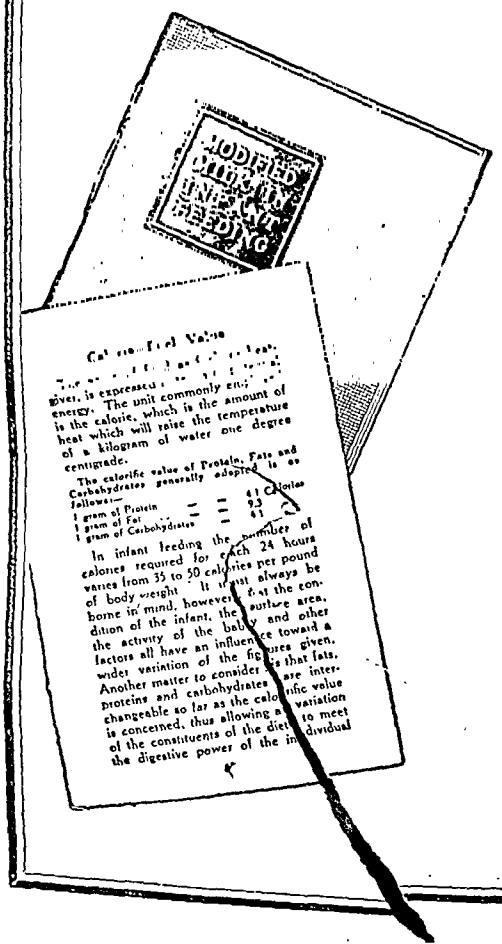
Irritable Bowel



Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

Mellin's Food

yields a complete and perfect diet for the hand-reared infant because it supplements the deficiencies of cow's milk, and is adaptable to the varying needs of the infant in health and in sickness. The mixture may be readily modified to meet the daily food requirements of any infant from birth onwards.

Corresponding to breast-milk in composition and properties, it is suitable for the most delicate babe from birth. The Mellin's Food prevents the formation of indigestible curd and assists the digestion of the milk.

Samples and booklet "Modified Milk in Infant Feeding" will be gladly forwarded to members of the medical profession on request.

TRADE Endomin MARK

Anaemia and its treatment. The use of liver has practically revolutionized the treatment of Anaemia, but it frequently gives rise to digestive disturbances. The metallic elements present in liver have a pronounced effect in increasing haemoglobin and red blood corpuscles.

Endomin—a hematopoietic based upon an entirely new principle—contains the essential metallic elements in a lipoid soluble readily assimilated tablet form. Packings of 100, 500 & 1,000 Tablets.

You are invited to send for a free stock size bottle to the Distributing Agents: Coates & Cooper, 41, Great Tower Street, London, E.C.3.

Manufactured by
REED AND CARNRICK
Pioneers in Endocrine Therapy
Jersey City, New Jersey.
South Africa: Lennon Ltd., Cape Town & Branches.

FORMULA

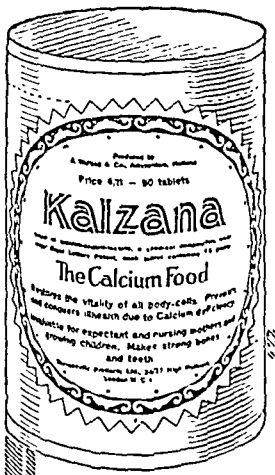
Each tablet contains in lipoid soluble form

Iron	8.0 mg.
Copper	0.6 mg.
Manganese	0.4 mg.
Zinc	0.3 mg.
Nickel	0.03 mg.
Cobalt	0.03 mg.
with the addition of Sodium Germanate	0.05 mg.

Roboleine
THE FOOD THAT BUILDS THE BODY

ROBOLEINE contains all essential vitamins:—BONE MARROW: Yellow marrow from the long bones to stimulate formation of red corpuscles and so strengthen the whole nervous system. Red marrow from the rib bones to stimulate formation of white corpuscles and increase resistance to disease. MALT, a natural laxative and source of energy. EGG YOLK, containing lecithin, the greatest nerve food known. LEMON JUICE, neutralised for building bone and preventing skin trouble.

ROBOLEINE corrects Metabolism and is recommended in cases of Malnutrition, Debility, Sleeplessness, Loss of Weight, and in all Tuberculous conditions; also to Nursing and Expectant Mothers as a galactagogue, and as an adjunct in the Dieting of Infants, etc.



ROBOLEINE is concentrated nourishment that revi[tal]ises body and feeds the nerves. Easily assimilable, [the] reconstructive tonic food available.

Samples sent gladly on request.

Calcium Deficiency in Women

Pregnancy and lactation often produce manifestations of calcium deficiency because the calcium reserve cannot meet the demands made upon it. The systematic use of Kalzana in these cases stays the destructive processes in the teeth and bones of the mother, and ensures normal development of the skeletal structure of the infant. The special feature of Kalzana is that it combines calcium lactate and sodium lactate in the form of a double salt, with the result that the sodium element improves the blood alkalinity to the extent necessary to secure adequate calcium retention.

The Practitioner says:

"*Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention.*"

Of Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

Rational Infant Feeding

The aim, in artificial feeding, is to produce as near as possible the equivalent of human milk, and therefore the most important constituent is the lactalbumin, because, apart from its protein value, it is responsible for breaking down the casein curd into minute, digestible particles. Albulactin is pure, soluble lactalbumin — the vital proteid of human milk — and when added to properly modified cow's milk it produces a milk mixture closely allied to human milk in composition and physiological effect. With Albulactin it is easy to meet every phase of infant feeding between the premature weakling and the normal robust infant.

The British Medical Journal says:

"*There appears to be every reason to expect this preparation to prove of great value in the 'Hand feeding' of infants.*"

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO. (Foreign Produce)

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available on special terms. Adequate samples for clinical trial sent with pleasure upon request.

(Aesculapius)

INJECTION TREATMENT OF

VARICOSE VEINS

Quinine and Urethane Method.

The injection treatment of Varicose Veins with a solution of Quinine and Urethane, introduced by Genevrier, gives excellent results. It is safe (no fatality after thousands of injections as yet has been recorded), it is non-toxic, non-caustic, and produces no general reaction or febrile disturbances.

VARIXOL

This is the scientifically prepared solution made at Evans' Biological Institute. It contains 4 grammes of Quinine Hydrochloride and 2 grammes of Urethane in a 30 c.c. bottle and is a stable and effective preparation. It is issued in 30 c.c. rubber-capped bottles and in ampoules of 1 c.c. and 2 c.c.

Sodium Morrhuate Method.

Sodium Morrhuate Solution is als used for the injection treatment of Varicose Veins. The effect is prompt and striking; it is harmless to the subcutaneous tissues, and very little discomfort arises from its injection.

EVANS' Sodium Morrhuate Solution 5%

is issued in rubber-capped bottles of 5 c.c., 10 c.c., 20 c.c., & 30 c.c. ampoules of 0.5 c.c., 1 c.c., and 2 c.c.

Further particulars on application to—

Prophylaxis against Dysentery by Oral Vaccines.

This method of establishing immunity against dysentery is very valuable since it has been found impossible to vaccinate by subcutaneous injections owing to the extraordinary toxic reactions produced thereby, whereas oral vaccines cause no inconvenience.

Oral Anti-Dysentery Vaccine (Genatosan) contains equal parts of Shiga's and Flexner's bacilli and is supplied in 5 c.c. bottles containing 100,000 million killed organisms.

Additional information regarding the above Vaccine will gladly be supplied to any Practitioner who writes to the Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

To VISITORS FROM ABROAD:

We shall welcome a visit from you so that we may bring to your notice a number of CHEMICALS, etc., which we make, and of which there are no equivalents elsewhere.

AMYL NITRITE "STERULES." As exported all over the world. Invaluable in relieving Angina Pectoris. Largely used in threatened fainting and collapse.

"AUREMETINE." A combination of Emetine and Auramine, used with success in Amoebic Dysentery.

"ASPRIODINE." A definite compound of Aspirin and Iodine, containing 41.47% of the latter. Largely used in Rheumatic affections and in Arterio-sclerosis.

CHAULMOOGRA DERIVATIVES. In Leprosy.

"METHYL-ASPRIODINE." Chemically this is Methyl Salicylate as official in many parts of the world with the salicyl radical converted into Aspirin and containing 39.7% Iodine. For local inunction.

MOSS DRESSINGS. The most absorbent Surgical Dressing in sheet form (compressed).

PEPTONE "STERULES." In Asthma. Graded doses ready for treatment, either intramuscular or intravenous.

"PHENYL-ASPRIODINE." An important new Aspirin derivative as an Urinary Antiseptic.

"SEDASPRIN." A member of our Halogenised Aspirins, containing 30.86% bromine.

"STERULES" of Gum Acacia, Glucose, *Indigo-Carmine, Phenolsulphonephthalein, etc.*

Milk

that is a supremely excellent Food for Infants.....

Libby's Evaporated Milk reaches the nursery scientifically clean. The curds are soft and flocculent as in human milk. The big fat globules are broken up by the process of homogenization into particles as small as those in mother's milk. That is why the fat of Libby's Milk is so easily assimilated even by the most delicate of infants. The two vitamins which milk can be depended upon to supply are present in abundance in Libby's Evaporated Milk, and as with any other milk, orange juice or tomato juice can be given to supply Vitamin C. You can safely prescribe Libby's Evaporated Milk for infants in your care.

The whole day's feeding can be prepared at once and will keep fresh and sweet.

Libby's Evaporated Milk

£1,000 *will be paid to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.*

No pulse irregularity after drinking this Coffee

There is no danger to the heart from caffein, because - -

IRREGULAR PULSE — AFTER DRINKING ORDINARY COFFEE

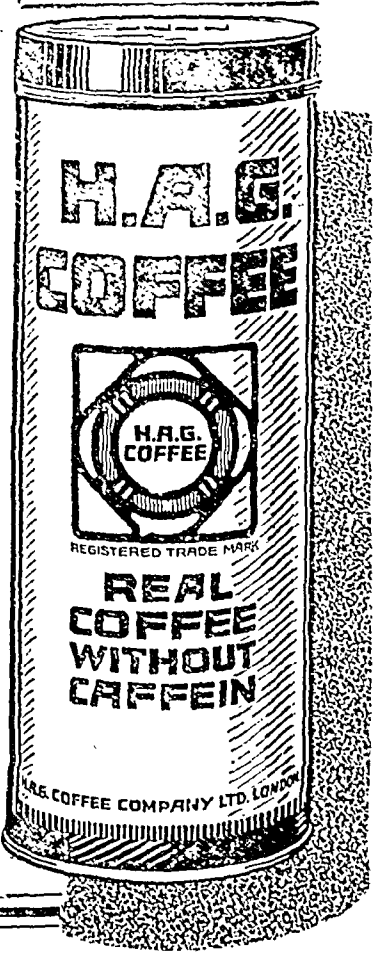
REGULAR PULSE — AFTER DRINKING H. A. G. COFFEE

H.A.G. COFFEE

is 97% decaffeinized

Ordinary coffee contains from 1% to 2% of caffein. It is largely because of this drug that coffee causes irregular palpitation (see chart above), increased blood pressure, irritation of the cardio-inhibitory vagus centre, and other conditions.

Yet, there is a coffee that patients can drink without danger from caffein. It is a delicious blend of fine coffees from which 97% of the caffein has been removed. H.A.G. COFFEE does not affect the pulse—as can be seen from the diagram at the right.



A REAL COFFEE WITH A REAL FLAVOUR

H.A.G. COFFEE is REAL coffee — not a substitute in any sense of the word. It is a choice blend of the finest Central American and South American coffees on the market. By extracting the caffein BEFORE ROASTING, all the original rich, delicious flavour and aroma has been retained

Patients who balk at substitutes will welcome the change to H.A.G. COFFEE, for it is superior to most ordinary coffees. In nearly every case they will find it more delicious than their customary blend.

Price per 6 oz. tin 1/4. either berry or ground.

Special 5 lb. tin for Medical Profession 13/6.

ORNAMENTED BAND ILLUSTRATING BYZANTINE MOSAIC WORK OF THE BEST PERIOD.—The Byzantines were supreme masters of the art of mosaic, which they employed for the decoration of all their great monuments. They did not invent, but they developed, the art, making it peculiarly their own and giving to it an individuality which can be clearly recognised in the work of the later mosaicists of the Italian school. Thence, for example, is derived the Florentine mosaic work, seen in the drawing of the figures and by the character of its inlaid designs. Recent researches show that certain exotic influences were embodied in what is known as Byzantine art, in addition to the elements inherited directly from Greece and Rome. In the case of mosaic, it seems most probable that the art originated in the East, whence it spread in several streams, one being towards Constantinople. Ravenna was the chief centre of this artistic impulse from the fourth to the end of the sixth century; it is from this city that the accompanying illustration is derived. Mosaic work was the Byzantines' most valuable art gift to posterity.

An Address
ON
COMPENSATION FOR INJURY.

DELIVERED BEFORE THE NOTTINGHAM MEDICAL SOCIETY
BY
V. WARREN LOW, C.B., M.D., F.R.C.S.,
CONSULTING SURGEON TO ST. MARY'S HOSPITAL, AND TO THE LONDON MIDLAND AND SCOTTISH RAILWAY COMPANY.

In a very early stage of civilization there appeared to be a feeling amongst men that some sort of amends should be made to the injured party for an injury wantonly inflicted. Many centuries had to pass before this idea also included accidental injuries. In Exodus xxi, 18, 19, we read:

"And if men strive together, and one smite another with a stone, or with his fist, and he die not, but keepeth his bed:
"If he rise again, and walk abroad upon his staff, then shall he that smote him be quit: only he shall pay for the loss of his time, and shall cause him to be thoroughly healed."

There you have the special damages, but not much for "pain and suffering." Then follow a few verses where other special forms of damage are mentioned, and, finally (verses 24 and 25), a sort of schedule of compensation:

"Eye for eye, tooth for tooth, hand for hand, foot for foot, burning for burning, stripe for stripe." And in Leviticus xxiv, 20: "As he hath caused a blemish in a man, so shall it be done to him again."

There is in all this a good deal of that vengeful spirit which is rather characteristic of the Old Testament.

No doubt for a long while in the world's history compensation lay chiefly in the direction of reparation for an intentional injury—a sort of business-like compromise for an act of revenge. Then there followed the rewards for military service, particularly when the soldier had been wounded, and this gradually developed into the idea that a man who had been disabled by military service had some sort of claim for maintenance on those in whose service the hurt had been sustained. But in all these examples the penalties were exacted for injuries inflicted intentionally, and it was an entirely new principle in law, at any rate in this country—and I believe that this country has usually been the pioneer in these matters!—when in 1846 Lord Campbell's Fatal Accidents Act was passed, which gave a right of action for compensation to the families of persons who are killed by the negligence of others.

WORKMEN'S COMPENSATION ACTS.

We as a profession are concerned only in the use of the term "compensation" in connexion with personal injuries, either in what are known as common law cases, but more particularly, because of their numbers, in connexion with cases under the Workmen's Compensation Acts. It is in these cases that the responsibility is thrown on our shoulders of giving advice as to the extent of the damage and the amount and duration of the disability caused thereby. Probably this is one of the most difficult and thankless tasks ever imposed on any profession. It involves, in the first place, a very accurate diagnosis, a difficult enough task in itself, but rendered none the less easy by the intense desire on the part of the patient that the damage done to him should not be underestimated, nor that any pathological peculiarity or blemish found on him should be dissociated from the accident.

Prognosis, always a thorny problem, is, in these cases, often complicated by the patient's apprehension that he may be getting well too quickly, or that the doctor is taking too cheerful a view of his case. There is always the feeling, either latent or openly expressed, that the transgressor must pay, and must pay well, till I sometimes wonder whether that old spirit of revenge is entirely confined to the Old Testament. Generally it can be said that the greater the injury the less the difficulty in assessing the damage; the patient is then too ill and too crippled to attempt to do the assessing for you, or, at any rate, is so confident of the reality of his disability that he can well afford to leave it to your judgement without any lead from him.

For a workman to uphold a claim under the Workmen's Compensation Act for personal injuries it is necessary for him to show that the injury was sustained as a result of (1) an accident arising out of and in the course of his employment*; (2) one of the industrial diseases brought specially within the scope of the Act. The word "accident" has received various interpretations, and at present the mishap or occurrence is looked at from the workman's standpoint, and, whatever its cause or origin, it is treated as accidental unless designed by the workman himself. This definition has been held to be wide enough to include such cases as heat-strokes, chill developing into inflammation of the kidneys, and the rupture of an advanced intrathoracic aneurysm. Practically it may be said that the injury is treated as the accident, and it does not matter that the injury was not caused by an accident, but resulted from merely normal and customary activities.

I think it may be stated as a fact that, owing to the number of cases that have been decided under the Acts, and to the manner in which the law has been codified and rendered more simple, the legal position of any plaintiff, except in very rare cases, is clear, provided that the facts can be proved. With very few exceptions the facts in dispute are in connexion only with the medical aspects of the case, and it is here that our difficulties begin. To the legal mind, untrained in medicine, it must sometimes appear that the opposing doctors, apparently in all good faith, are expressing views which are poles apart on the same circumstances. Often the difference is more apparent than real, and depends more on different methods of expression or on inequalities of emphasis than on any real divergence of opinion on what are the essentials of the case.

Quite apart from this, however, there is, in this class of case, plenty of room for an honest difference of opinion with regard to even the essential points at issue. This difficulty is not lessened when the plaintiff, either from ignorance, stupidity, or from motives less naive, exaggerates or imagines the symptoms which are responsible for his incapacity. Yet it is on controversial material like this that a tribunal, untrained in medicine, may have to come to a decision. I am referring to those cases where a county court judge sits without a medical referee. There are, however, some county court judges who do not consult their referee, even when he is sitting, and I know of one judge who believes, or affects to believe, that the only function of the medical referee is to explain the meaning to the judge of such medical terms as the latter does not understand. From this decision on the medical evidence there is no appeal, as the courts above assume the findings of the county court judge as the facts of the case.

The difficulties in connexion with these cases arrange themselves under two heads: (1) The question of entitlement. Is the workman's disability the result of accident, or has it been aggravated by accident, or is it due to some other cause? This is often largely a matter of diagnosis. (2) The question of duration of incapacity. This is a matter of vast difference of opinion between employees and employed. It is often a matter of very considerable difficulty for a conscientious surgeon to decide at what period the injured workman ought to be forced, under the penalty of losing his weekly compensation, to resume his normal employment. One occasionally, I am glad to say not often, comes across a case of frank malingering, but one sees numbers of cases in which a few weeks' inactivity appears to promote an "inertia" and "work shyness" which are exceedingly difficult to overcome, and to which the certifying doctor often shrinks, for some months, from applying the drastic remedy of refusing a certificate. It would be impossible to compute the number of working days that are thus lost to the community or the thousands of pounds thus paid in unnecessary compensation, and, what I think is of greater importance, the damage done to the workman's own morale. I am not suggesting that

*The phrase "arising out of and in the course of his employment" has been the subject of so much judicial consideration that its meaning is well settled.

this is peculiar to cases which come under the Workmen's Compensation Acts. There is always a startling contrast in the time taken to resume the normal occupation after accidents incurred at football, polo, hunting, etc., where the responsibility of the incapacity rests with the patient, to the time taken to recover from accidents for which the responsibility rests with others. It is the enormous number of Workmen's Compensation Act cases that renders the matter of so much importance.

It is very often the first certificate that ties the doctor's hands. Given, perhaps, on the first occasion, after a hurried examination of the patient and with a vague, half-formed excuse to one's own conscience that the patient should have the benefit of the doubt, the certificate reads to the effect that "A.B. is suffering from the effects of an accident of a certain date, and that he is unable to follow his employment." Even A.B. is a trifle astonished. He had given expression to what to him was but a half-formed idea that his pain in the back, never very serious, must have been due to a slight strain that he had experienced the other afternoon. He had rather expected to be cross-examined on the subject, and had felt very uncertain of his ground, and would have been quite willing to be guided by the doctor's opinion, but here it was in black and white with the doctor's signature beneath it. From that moment his doubts in the matter diminish, and as his certainty grows so does his incapacity, and it becomes increasingly difficult for the doctor to recede from the position in which his first certificate has placed him. Finally, the fear of being thought inconsistent and not knowing his own mind drives the doctor into the witness-box, where his counsel coaxes him into a position far in advance of that which he had intended to take, and where he is still more strongly entrenched by his reaction to the bullying tactics of the cross-examining counsel. In the meanwhile A.B. feels that he ought to do his best to support the very handsome testimonial of incapacity given him by his doctor in the witness-box, under circumstances which A.B. regards as heroic, and he becomes more than ever firmly entrenched in a fortress of incapacity from which it will take many months to dislodge him.

This may appear to be an extreme case, and possibly, to many of you, a mere fantasy, but I can assure you that I have seen compensation cases grow up in this manner until finally, whatever may have been the periods of doubt through which they passed in the process, the two who are most convinced of the justice of their cause are the patient and the doctor. But, as I have said before, it is often on the different meaning applied to medical terms that we, as a profession, fail in the eyes of the public, owing to our inability to agree. Take, for example, the use and misuse of the term "shock."

"SHOCK."

Shock, as I think most of us understand it, is a condition of profound physical depression resulting immediately from some serious accident or operation. The patient either dies or gradually recovers from such a condition. With this conception of the meaning of the term it is impossible to believe that a person can remain, for months or even for weeks, in such a condition. The term "delayed shock" is obviously a misnomer, although it has been used in text-books, but the pathology of the conditions for which the term "delayed shock" stood is now known not to be the same as that of shock. Shock, however, as we meet it in the law courts, and as it is understood by every solicitor's clerk, is a very mixed bag of nervous phenomena following any accident, however trivial, usually coming on slowly and insidiously, and often after an interval—an interval which Charcot used to call, with, I should like to think, a sly humour, "a period of meditation." This sort of shock often produces a condition of so-called "nerve exhaustion" to which that vague and misused term "neurasthenia" is applied. I should like to contrast a case of real surgical shock with one of the cases where the term "shock" is used only in its legal sense.

I saw, last year, a girl of 14, who had been involved in a very serious railway accident early in January, 1929. The accident had occurred in the small hours of the morning in a fog, when the temperature was below freezing point. To the ordinary horrors of a railway accident were added those of fire, and many of the injured were burnt to death. The accident happened on January 8th, and I saw the child on January 26th. I also interviewed the doctors who had administered first aid, and under whose care the child had come, at the local hospital.

She had already been removed from the wreckage of the train by the time the doctors arrived on the scene of the accident, and was lying on some hot-water pipes in the waiting room of the station where the accident had happened. The child was then quite cold, livid in colour, and pulseless; her breathing could not then be detected, and her limbs were flaccid and her pupils dilated. I was assured by both doctors that for some time they were unable to decide whether she was alive. She was actually, at one moment, destined for the ambulance in which the dead were being removed to the mortuary. Some doubt existed, however, and she was allowed to remain on the hot-water pipes. She presently showed more signs of life, and was removed to the hospital. She remained for a few days in a critical condition. Her abdomen and right loin were extensively bruised, and she had passed blood from both her bladder and intestine. It was feared, therefore, that she had ruptured some internal abdominal organ, but her condition of extreme shock made it impossible to carry out any further investigations, and treatment only of the shock was undertaken.

When I saw her nearly three weeks afterwards she showed very little evidence of the extremely critical period through which she had passed. Her pulse, respirations, and temperature were normal. There was some slight tenderness of her abdomen, and some faint discoloration over the right lumbar region. It was then obvious that no internal organ had been seriously injured, though possibly there had been extensive bruising of some of the viscera, and this was corroborated by the haematuria and melaena. She had, however, unfortunately, two large superficial burns on her left buttock. For these, I presume, the hot-water pipes were responsible, but as probably the hot-water pipes had to be thanked for the preservation of her life the balance of merit was with them. When I saw the child, in spite of the considerable discomfort of her burns, she was lying placidly in bed reading. She talked to me cheerfully, and made no allusion to her illness or to her being in hospital. I was told that she evidently had no memory of the accident, and no allusion to this was ever made to her. She ultimately recovered and did well without any of the nervous phenomena usually associated with shock in connexion with railway accidents.

The case, I think, illustrates two points: first, how completely may be the recovery from shock of the most extreme degree; and secondly, how much depends on the environment of the patient during the period of recovery. Had the child not remained in the judicious calm by which she was surrounded at this little hospital, she might have been exposed to emotional stresses, quite unconnected with the accident, which would have reacted on her and produced a symptom complex which is thought by some to be the peculiar product of railway accidents. The consequence would have been a long period of mental ill health for a child at, perhaps, the most critical period of her life.

May I contrast this case with another from the same accident?

In this case an elderly gentleman claimed a large amount in compensation for disability resulting from shock sustained in this accident. I did not see the patient until May 24th, when I examined him in a Midland town with another surgeon. The patient was a very healthy-looking man of 67 years of age. He was able to give us a very detailed and dramatic account of the accident so far as it affected himself. He told us exactly what he was doing just before the accident. He remembered all the details of the accident itself, and all that happened immediately afterwards. He remembered his anxieties and fears, the cold and the fog, and how he was extricated from the wreckage. He was able, with assistance, to walk the fifty yards to the railway station, and was taken to the same hospital as the child. Here two scalp wounds were sewn up without an anaesthetic, and after four days in hospital he returned to his own home by car.

His solicitors claimed for him that he had been severely shocked in the accident, and that his present symptoms were the sequelae of the shock. Mr. X himself complained that he was possessed of a "horrible sense of fear," which was brought on by the slightest noise when he was awake, and which possessed him like a nightmare when he was asleep. On being asked for any further consequences of the accident Mr. X produced some notes from his pocket, and then complained of "lack of confidence in himself" and "that he dreaded travelling." In answer to a question he explained that his reference to his notes for such apparently

important symptoms was due to his "lack of concentration and memory." He made no complaint of headache, giddiness, or of inability to sleep.

As a result of all this he had given up his business and had had to retire since the accident. He was a brisk, cheerful-looking man, who scarcely looked his age. He was well nourished, and said that he weighed 14 stone. He thought that he had put on weight since the accident. There were two small scars on his head, which were not tender nor adherent to the skull. We could find nothing abnormal with his nervous system. We also considered his mental condition to be singularly alert, and at that interview he showed certainly neither want of confidence nor want of concentration. There was nothing in his condition when we saw him, except what Mr. X himself told us, which would suggest that less than six months previously he had been involved in such a serious accident.

It was, of course, quite impossible to traverse such statements that he was "nervous," "suffering from nightmares," and "unable to travel," but his very detailed description of the accident was not consistent with his "lack of concentration" and "loss of memory." Nor was it consistent that a man who could remember all the details of his accident, and the reasons why he did this or refrained from doing that, should have to resort to his notes to remember such important symptoms as "loss of concentration and confidence" and "dread of travelling."

This is an excellent example of the misuse of the term shock. It was used by the lawyers in exactly the same sense as the term was used in the case of the child. Mr. X had obviously and fortunately escaped even the slightest degree of shock. He had, no doubt, passed through a very trying experience, and the fright of the accident and the scenes he had witnessed might well have produced on him a mental effect which must, at the time, have been very upsetting, and may have produced the "sense of fear" and "the nightmares" of which he complained. In our opinion, when we saw him these effects were passing off, if they had not already done so, and Mr. X was confusing, in his mind, memories of the immediate past with the present. It would probably have been wiser for an ordinary man, at that time, to have resumed his occupation. Unfortunately, Mr. X was 67 years of age, and we realized how difficult it was for a man of that age, after a period of rest, to resume what were, perhaps, already waning activities.

My point, however, is to emphasize the misuse of the term shock by the lawyers, the public, and occasionally, I am afraid, by our own profession. Had this case come into court I should have been confronted with medical evidence to the effect that Mr. X was suffering from the sequelae of severe shock caused by the accident. What else should you expect, say the public, from a railway accident but shock? This is true enough if one uses the term in the sense in which we all use it when we find that our income tax has been raised, but this kind of shock, serious as it may be, does not carry with it the mortality nor the sequelae of surgical shock. I should like to add that I believe that, with proper treatment, surgical shock produces very little in the way of nervous sequelae. We have all seen many cases of severe surgical shock. The treatment, if the patient survives, is that of the condition which caused the shock; and how many cases have we seen in which there are marked nervous symptoms afterwards which could be ascribed to the shock itself? I should say very few.

The misuse of the term, however, whether conscious or not, is a distinct legal asset to the plaintiff. It at once emphasizes the severity of the original injury, and at the same time forms a useful link between the accident and any rather possibly remote nervous phenomena which may occur. The severity of this kind of shock is often measured by the narrowness of the patient's escape from danger. That a car or a wheel should have missed someone by a few inches is a great "shock" producer.

Concussion.

"Concussion" is another term which is constantly mishandled by the legal profession and by the public. Mr. Trotter[2] has described concussion as "indicating an essentially transient state, due to head injury, which is of instantaneous onset, manifests widespread symptoms of a purely paralytic kind, does not, as such, comprise any evidence of structural cerebral injury, and is always followed by amnesia of the actual moment of the accident." The essential features of concussion are its suddenness and the loss of consciousness, however brief.

Mr. Trotter has made use of the term "retrograde amnesia" to express the loss of memory of events immediately preceding the accident. When I was a registrar at St. Mary's I collected a number of instances of this. They varied between, in a slight case, the loss of memory of the events of the four or five minutes immediately preceding the accident, as could be measured by the time it took the patient to walk the distance from the last point remembered to the scene of the occurrence, to, in a more serious case, the loss of memory of the events of weeks before. It often happens that the victim of a railway accident which has happened after he has been on his journey for some hours can remember events only up to the time when he left his own home in the morning and took his ticket at the station.

The sequelae of a head injury, with or without concussion, are many, and since the war we have accustomed ourselves to the use of the term "cerebral contusion," which has partly taken the place of the older term "cerebral laceration," and which has also gone some way to explain the pathology of conditions which previously were regarded as functional. I think we owe a good deal of this again to Mr. Trotter. The symptoms which used to be described as those of cerebral irritation are now regarded as "contusion effects." The chief of these is what is known as "contusion headache."

For some unexplained reason the headaches in these cases of cerebral contusion may often occur after a latent interval.[3] They are not, as a rule, continuous, but intermittent. They are often associated with a certain amount of mental impairment and with giddiness, and with the latter are usually in relation with some alteration of posture, such as stooping, or turning the head suddenly to one side. The mental impairment usually takes the form of defective memory, inability to concentrate, and some diminution of emotional control. All of these are more or less indications of mental fatigue. Such a condition is to be distinguished from the headache of a functional neurosis following a head injury. The neurotic headache usually dates from the time of the accident, is continuous rather than intermittent, has little or no relation to posture, and is aggravated by any emotional stress. What is most important in the neurotic headache is the absence of any evidence of mental impairment or fatigue. The neurotic patient has usually the most acute memory for anything connected with his disability and anything that may have caused it. During the examination he is keenly alert, and often displays, in an unusual degree, that power of concentration which, according to his notes, should be missing. The following cases illustrate the distinction between the two types.

"A man, 44 years of age, was injured on November 24th, 1925, in an accident in which one train ran into the rear of another. He was in the back part of the front train. At the time of the accident he lost consciousness for a brief period of time. When he came to his mouth was bleeding and his teeth were loose, in fact one tooth came out in the night. There were some wounds and abrasions of the mucous membrane lining his cheek, and his nose was bleeding. He remained at his home in the country until January 3rd. He did not keep his bed, and used to go to the doctor's house. His chief complaint was pain in the head. On January 3rd he came up to London on business, but the journey upset him, and he remained at home for another week. He then came up to town four times a week. In February he was not so well, and had to consult a neurologist. He took three weeks' holiday at Whitsuntide, and was better. While returning from his holiday some jolting of the train, owing to a defective brake, restarted the pains in his head, and he had not been so well since.

When I saw him on July 24th, 1927, he complained of pain over the posterior part of his head and shooting pains over his eyes. He also felt a sense of constriction round his head. The pain came and went, and he might go for days without it. During our interview he said that he had a "pressing down pain on the top of his head," and that this sensation of pressure was worse when he stooped. He said that he suffered from loss of memory, but that his memory was better than it had been, although he was still liable to make mistakes. There was no tenderness over the

painful area of his scalp, and I could find no evidence of any organic disease of his nervous system. He gave me the impression of candour and frankness, and made no attempt to exaggerate his symptoms. These appeared to me, and to the neurologist who examined him with me, to correspond with the symptoms due to a cerebral contusion.
